

PSEUDOHOLOMORPHIC QUILTS

KATRIN WEHRHEIM AND CHRIS T. WOODWARD

We define relative Floer theoretic invariants arising from “quilted pseudoholomorphic surfaces”: Collections of pseudoholomorphic maps to various target spaces with “seam conditions” in Lagrangian correspondences. As application we construct a morphism on quantum homology associated to any monotone Lagrangian correspondence.

1. Introduction

Lagrangian Floer cohomology associates to a pair of Lagrangian manifolds a chain complex whose differential counts pseudoholomorphic strips with boundary values in the given Lagrangians. These form a receptacle for *relative invariants* defined from surfaces with strip-like ends, see e.g. [15]. The simplest instance of this invariant proves the independence of Floer cohomology from the choices of almost complex structure and perturbation data. More complicated cases of these invariants construct the product on Floer cohomology, and the structure maps of the Fukaya category.

This paper is one of a sequence in which we generalize these invariants to include Lagrangian correspondences. The first papers in the sequence were [19], [17]; however, we have tried to make the paper as self-contained as possible. Recall that if (M_0, ω_0) and (M_1, ω_1) are symplectic manifolds, then a *Lagrangian correspondence* from M_0 to M_1 is a Lagrangian submanifold of $M_0^- \times M_1$, where $M_0^- := (M_0, -\omega_0)$. Whereas Lagrangian manifolds form elliptic *boundary conditions* for pseudoholomorphic curves, Lagrangian correspondences form elliptic *seam conditions*. For a pair of curves with boundary in M_0 and M_1 , a seam condition L_{01} roughly speaking requires corresponding boundary values to pair to a point on $L_{01} \subset M_0^- \times M_1$. (Differently put, a neighbourhood of the seam can be “folded up” to a pseudoholomorphic curve in $M_0^- \times M_1$ with boundary values on L_{01} .) Using such seam conditions between pseudoholomorphic strips, we defined in [19] a *quilted Floer cohomology* $HF(L_{01}, L_{12}, \dots, L_{(k-1)k})$ for a cyclic sequence of Lagrangian correspondences $L_{(\ell-1)\ell} \subset M_{\ell-1}^- \times M_\ell$ between symplectic manifolds $M_0, M_1, \dots, M_k = M_0$. In this paper we construct new Floer type invariants arising from quilted pseudoholomorphic surfaces. These quilts consist of pseudoholomorphic surfaces (with boundary and strip-like ends in various target spaces) which satisfy seam conditions (mapping certain pairs of boundary components to Lagrangian correspondences) and boundary conditions (mapping other boundary components to simple Lagrangian submanifolds). Similar moduli spaces appeared in the work of Perutz [8] and have been considered by Khovanov and Rozansky [5] under the name of *pseudoholomorphic foams*. The present paper provides a general language, invariance and gluing theorems for pseudoholomorphic quilts. Moreover, we establish an

invariance of relative quilt invariants under strip shrinking and geometric composition of Lagrangian correspondences. The geometric composition of two Lagrangian correspondences $L_{01} \subset M_0^- \times M_1$, $L_{12} \subset M_1^- \times M_2$ is

$$L_{01} \circ L_{12} := \{(x_0, x_2) \in M_0 \times M_2 \mid \exists x_1 : (x_0, x_1) \in L_{01}, (x_1, x_2) \in L_{12}\}.$$

In general, this will be a singular subset of $M_0^- \times M_2$, with isotropic tangent spaces where smooth. However, if we assume transversality of the intersection $L_{01} \times_{M_1} L_{12} := (L_{01} \times L_{12}) \cap (M_0^- \times \Delta_{M_1} \times M_2)$, then the restriction of the projection $\pi_{02} : M_0^- \times M_1 \times M_1^- \times M_2 \rightarrow M_0^- \times M_2$ to $L_{01} \times_{M_1} L_{12}$ is automatically an immersion. If in addition π_{02} is injective, then $L_{01} \circ L_{12}$ is a smooth Lagrangian correspondence and we will call it an *embedded* geometric composition. If the composition $L_{(\ell-1)\ell} \circ L_{\ell(\ell+1)}$ is embedded, then under suitable monotonicity assumptions there is a canonical isomorphism

$$(1) \quad HF(\dots, L_{(\ell-1)\ell}, L_{\ell(\ell+1)}, \dots) \cong HF(\dots, L_{(\ell-1)\ell} \circ L_{\ell(\ell+1)}, \dots).$$

For the precise monotonicity and admissibility conditions see [19] or Section 4. The proof in [17, 19] proceeds by shrinking the strip in M_ℓ to width zero and replacing the two seams labeled $L_{(\ell-1)\ell}$ and $L_{\ell(\ell+1)}$ with a single seam labeled $L_{(\ell-1)\ell} \circ L_{\ell(\ell+1)}$. In complete analogy, Theorem 5.1 shows that the same can be done in a more general quilted surface: The two relative invariants arising from the quilted surfaces with or without extra strip are intertwined by the above isomorphism (1) of Floer cohomologies.

A first application of pseudoholomorphic quilts is the proof of independence of quilted Floer homology from the choices of strip widths in [19]. As a second example we construct in Section 6 a morphism on quantum homologies $\Phi_{L_{01}} : HF(\Delta_{M_0}) \rightarrow HF(\Delta_{M_1})$ associated to a Lagrangian correspondence $L_{01} \subset M_0^- \times M_1$. This is in general not a ring morphism, simply for degree reasons, and even on the classical level. However, using the invariance and gluing theorems for quilts, we show that it factors $\Phi_{L_{01}} = \Theta_{L_{01}} \circ \Psi_{L_{01}}$ into a ring morphism $\Psi : HF(\Delta_{M_0}) \rightarrow HF(L_{01}, L_{01})$ and a morphism $\Theta : HF(L_{01}, L_{01}) \rightarrow HF(\Delta_{M_1})$ satisfying

$$\Theta(x \circ y) - \Theta(x) \circ \Theta(y) = x \circ T_{L_{01}} \circ y,$$

where the right hand side is a composition on quilted Floer cohomology with an element $T_{L_{01}} \in HF(L_{01}^t, L_{01}, L_{01}^t, L_{01})$ that only depends on L_{01} . We hope this will be useful in studying Ruan's conjecture [4] that quantum cohomology rings are invariant under birational transformations with good properties with respect to the first Chern class.

In the sequel [18] we construct a symplectic 2-category with a categorification functor via pseudoholomorphic quilts. In particular, any Lagrangian correspondence $L_{01} \subset M_0^- \times M_1$ gives rise to a functor $\Phi(L_{01}) : \text{Don}^\#(M_0) \rightarrow \text{Don}^\#(M_1)$ between (somewhat extended) Donaldson-Fukaya categories. Given another Lagrangian correspondence $L_{12} \subset M_1^- \times M_2$, the algebraic composition $\Phi(L_{01}) \circ \Phi(L_{12}) : \text{Don}^\#(M_0) \rightarrow \text{Don}^\#(M_2)$ is always defined, and if the geometric composition $L_{01} \circ L_{12}$ is embedded then $\Phi(L_{01}) \circ \Phi(L_{12}) \cong \Phi(L_{01} \circ L_{12})$. In other words, embedded geometric composition is isomorphic to the algebraic composition in the symplectic category, and ‘‘categorification commutes with composition’’.

We thank Paul Seidel and Ivan Smith for encouragement and helpful discussions, and the referee for most valuable feedback.

1.1. Notation and monotonicity assumptions. One notational warning: When dealing with functors we will use functorial notation for compositions, that is $\Phi_0 \circ \Phi_1$ maps an object x to $\Phi_1(\Phi_0(x))$. When dealing with simple maps like symplectomorphisms, we will however stick to the traditional notation $(\phi_1 \circ \phi_0)(x) = \phi_1(\phi_0(x))$.

For Lagrangian correspondences and (quilted) Floer cohomology we will use the notation developed in [19]. Moreover, we will frequently refer to assumptions on monotonicity, Maslov indices, and grading of symplectic manifolds M and Lagrangian submanifolds $L \subset M$. We briefly summarize these here from [19].

- (M1): (M, ω) is *monotone*, that is $[\omega] = \tau c_1(TM)$ for some $\tau \geq 0$.
- (M2): If $\tau > 0$ then M is compact. If $\tau = 0$ then M is (necessarily) noncompact but satisfies “bounded geometry” assumptions as in [15, Chapter 7].¹
- (L1): L is *monotone*, that is $2 \int u^* \omega = \tau I(u)$ for all $[u] \in \pi_2(M, L)$. Here $I : \pi_2(M, L) \rightarrow \mathbb{Z}$ is the Maslov index and $\tau \geq 0$ is (necessarily) as in (M1).
- (L2): L is compact and oriented.
- (L3): L has (effective) minimal Maslov number $N_L \geq 3$. Here N_L is the generator of $I(\{[u] \in \pi_2(M, L) \mid \int u^* \omega > 0\}) \subset \mathbb{N}$.

When working with Maslov coverings and gradings we will restrict our considerations to those that are compatible with orientations as follows.

- (G1): M is equipped with a Maslov covering $\text{Lag}^N(M)$ for N even, and the induced 2-fold Maslov covering $\text{Lag}^2(M)$ is the one described induced by the orientation of M .
- (G2): L is equipped with a grading $\sigma_L^N : L \rightarrow \text{Lag}^N(M)$, and the induced 2-grading $L \rightarrow \text{Lag}^2(M)$ is the one given by the orientation of L .

Finally, note that our conventions differ from Seidel’s definition of graded Floer cohomology in [13] in two points which cancel each other: The roles of x_- and x_+ are interchanged and we switched the sign of the Maslov index in the definition of the degree.

2. Invariants for surfaces with strip-like ends

We begin with a formal definition of surfaces with strip-like ends analogous to [14, Section 2.4] (in the exact case) and [12] (in the case of surfaces without boundary). To reduce notation somewhat we restrict to strip-like ends, i.e. punctures on the boundary. One could in addition allow cylindrical ends by adding punctures in the interior of the surface, see Remark 2.11.

Definition 2.1. A *surface with strip-like ends* consists of the following data:

- a) A compact Riemann surface \bar{S} with boundary $\partial \bar{S} = C_1 \sqcup \dots \sqcup C_m$ and $d_n \geq 0$ distinct points $z_{n,1}, \dots, z_{n,d_n} \in C_n$ in cyclic order on each boundary circle $C_n \cong S^1$. We will use the indices on C_n modulo d_n , index all marked points by

$$\mathcal{E} = \mathcal{E}(S) = \{e = (n, l) \mid n \in \{1, \dots, m\}, l \in \{1, \dots, d_n\}\},$$

and use the notation $e \pm 1 := (n, l \pm 1)$ for the cyclically adjacent index to $e = (n, l)$. We denote by $I_e = I_{n,l} \subset C_n$ the component of ∂S between $z_e = z_{n,l}$ and $z_{e+1} = z_{n,l+1}$. However, ∂S may also have compact components $I = C_n \cong S^1$.

- b) A complex structure j_S on $S := \bar{S} \setminus \{z_e \mid e \in \mathcal{E}\}$.
- c) A set of *strip-like ends* for S , that is a set of embeddings with disjoint images

$$\epsilon_e : \mathbb{R}^\pm \times [0, \delta_e] \rightarrow S$$

for all $e \in \mathcal{E}$ such that $\epsilon_e(\mathbb{R}^\pm \times \{0, \delta_e\}) \subset \partial S$, $\lim_{s \rightarrow \pm\infty} (\epsilon_e(s, t)) = z_e$, and $\epsilon_e^* j_S = j_0$ is the canonical complex structure on the half-strip $\mathbb{R}^\pm \times [0, \delta_e]$ of width² $\delta_e > 0$. We denote the set of incoming ends $\epsilon_e : \mathbb{R}^- \times [0, \delta_e] \rightarrow S$ by $\mathcal{E}_- = \mathcal{E}_-(S)$ and the set of outgoing ends $\epsilon_e : \mathbb{R}^+ \times [0, \delta_e] \rightarrow S$ by $\mathcal{E}_+ = \mathcal{E}_+(S)$.

¹More precisely, we consider symplectic manifolds that are the interior of Seidel’s compact symplectic manifolds with boundary and corners. We can in fact deal with more general noncompact exact manifolds, such as cotangent bundles or symplectic manifolds with convex ends. For that purpose note that we do not consider cylindrical ends mapping to noncompact symplectic manifolds, so the only technical requirement on exact manifolds is that the compactness in Theorem 3.9 holds, see the footnote in the proof there.

²Note that here, by a conformal change of coordinates, we can always assume the width to be $\delta_e = 1$. The freedom of widths will only become relevant in the definition of quilted surfaces with strip-like ends.

- d) An ordering of the set of (compact) boundary components of \overline{S} and orderings $\mathcal{E}_- = (e_1^-, \dots, e_{N_-}^-)$, $\mathcal{E}_+ = (e_1^+, \dots, e_{N_+}^+)$ of the sets of incoming and outgoing ends. Here $e_i^\pm = (n_i^\pm, l_i^\pm)$ denotes the incoming or outgoing end at $z_{e_i^\pm}$.

Elliptic boundary value problems are associated to surfaces with strip-like ends as follows. Let E be a complex vector bundle over S and $\mathcal{F} = (F_I)_{I \in \pi_0(\partial S)}$ a tuple of totally real subbundles $F_I \subset E|_I$ over the boundary components $I \subset \partial S$. Suppose that the sub-bundles $F_{I_{e-1}}, F_{I_e}$ are constant and intersect transversally in a trivialization of E near z_e .³ Let

$$D_{E, \mathcal{F}} : \Omega^0(S, E; \mathcal{F}) \rightarrow \Omega^{0,1}(S, E)$$

be a real Cauchy-Riemann operator acting on sections with boundary values in F_I over each component $I \subset \partial S$. Transversality on the ends implies that the operator $D_{E, \mathcal{F}}$ is Fredholm. If $S = \overline{S}$ has no strip-like ends, and $S_0 \subset S$ denotes the union of components without boundary, we denote by $I(E, \mathcal{F})$ the topological index

$$I(E, \mathcal{F}) = \deg(E|_{S_0}) + \sum_{I \in \pi_0(\partial S)} I(F_I),$$

where $I(F_I)$ is the Maslov index of the boundary data determined from a trivialization of $E|(S \setminus S_0) \cong (S \setminus S_0) \times \mathbb{C}^r$. The index theorem for surfaces with boundary [6, Appendix C] implies

$$(2) \quad \text{Ind}(D_{E, \mathcal{F}}) = \text{rank}_{\mathbb{C}}(E)\chi(S) + I(E, \mathcal{F}).$$

Note that the topological index $I(E, \mathcal{F})$ is automatically even if the fibers of \mathcal{F} are oriented, since loops of oriented totally real subspaces have even Maslov index and complex bundles have even degree.

A special case of these oriented totally real boundary conditions will arise from oriented Lagrangian submanifolds. We fix a compact, monotone (or noncompact, exact) symplectic manifold (M, ω) satisfying (M1-2) and let M be equipped with an N -fold Maslov covering satisfying (G1). For every boundary component $I \subset \pi_0(\partial S)$ let $L_I \subset M$ be a compact, monotone, graded Lagrangian submanifold satisfying (L1-2) and (G2). We will also write $L_e := L_{I_e}$ for the Lagrangian associated to the noncompact boundary component $I_e \cong \mathbb{R}$ between z_{e-1} and z_e .

These assumptions ensure that the grading $|x| \in \mathbb{Z}_N$ on the Floer chain groups $HF(L_e, L_{e'})$ induces a \mathbb{Z}_2 -grading $(-1)^{|x|}$ which only depends on the orientations of $(L_e)_{e \in \mathcal{E}(S)}$. Moreover, we say that the tuple $(L_I)_{I \in \pi_0(\partial S)}$ is *relatively spin* if all Lagrangians L_I are relatively spin with respect to one fixed background class $b \in H^2(M, \mathbb{Z}_2)$, see [20] for more details.

With these preparations we can construct moduli spaces of pseudoholomorphic maps from the surface S . For each pair (L_{e-1}, L_e) for $e \in \mathcal{E}_+$ resp. (L_e, L_{e-1}) for $e \in \mathcal{E}_-$ choose a regular pair (H_e, J_e) of Hamiltonian and almost complex structure (as in [19]) such that the graded Floer cohomology $HF(L_{e-1}, L_e)$ resp. $HF(L_e, L_{e-1})$ is well defined. Here $J_e : [0, \delta_e] \rightarrow \mathcal{J}(M, \omega)$ is a smooth family in the space of ω -compatible almost complex structures on M . Let $\text{Ham}(S; (H_e)_{e \in \mathcal{E}})$ denote the set of $C^\infty(M)$ -valued one-forms $K_S \in \Omega^1(S, C^\infty(M))$ such that $K_S|_{\partial S} = 0$ and $\epsilon_{S,e}^* K_S = H_e dt$ on each strip-like end. Let $Y_S \in \Omega^1(S, \text{Vect}(M))$ denote the corresponding Hamiltonian vector field valued one-form, then $\epsilon_{S,e}^* Y_S$ equals to $X_{H_e} dt$ on each strip-like end. We denote by $\mathcal{J}(S; (J_e)_{e \in \mathcal{E}})$ the subset of $J_S \in C^\infty(S, \mathcal{J}(M, \omega))$ that equals to the given perturbation datum J_e on each strip-like end.

We denote by \mathcal{I}_- the set of tuples $X^- = (x_e^-)_{e \in \mathcal{E}_-}$ with $x_e^- \in \mathcal{I}(L_e, L_{e-1})$ and by \mathcal{I}_+ the set of tuples $X^+ = (x_e^+)_{e \in \mathcal{E}_+}$ with $x_e^+ \in \mathcal{I}(L_{e-1}, L_e)$. For each of these tuples we denote by

$$\mathcal{M}_S(X^-, X^+) := \{u : S \rightarrow M \mid (a) - (d)\}$$

³As pointed out to us by the referee, one can avoid the use of trivializations here by assuming that the bundles F_I are defined over the closure $\overline{I} \subset \overline{S}$ (which is diffeomorphic to a closed interval) and intersect transversely at the points of $\overline{S} - S$.

the space of (J_S, K_S) -holomorphic maps with Lagrangian boundary conditions, finite energy, and fixed limits, that is

- a) $\bar{\partial}_{J,K} u := J_S(u) \circ (du - Y_S(u)) - (du - Y_S(u)) \circ j_S = 0$,
- b) $u(I) \subset L_I$ for all $I \in \pi_0(\partial S)$,
- c) $E_{K_S}(u) := \int_S (u^* \omega + d(K_S \circ u)) < \infty$,
- d) $\lim_{s \rightarrow \pm\infty} u(\epsilon_{S,e}(s, t)) = x_e^\pm(t)$ for all $e \in \mathcal{E}_\pm$.

Remark 2.2. 1) For any map $u : S \rightarrow M$ that satisfies the Lagrangian boundary conditions (b) and exponential convergence to the limits in (d) (and hence automatically also satisfies (c)) one constructs a linearized operator D_u as in [6] with a minor modification to handle the boundary conditions: For any section ξ of $E_u = u^*TM$ satisfying the linearized boundary conditions in $\mathcal{F}_u = ((u|_I)^*TL_I)_{I \in \pi_0(\partial S)}$ set $\sigma_u(\xi) = \Phi_u(\xi)^{-1} \bar{\partial}_{J,K}(\exp_u(\xi))$. For the moduli space to be locally homeomorphic to the zero set of σ_u , we need to define the exponential map \exp such that $\exp(TL_I) \subset L_I$, and $\Phi_u(\xi)$ has to be parallel transport of $(0, 1)$ -forms from base point u to base point $\exp_u(\xi)$. To satisfy the first requirement we choose metrics g_I on M that make the Lagrangians L_I totally geodesic and define the exponential map $\exp : S \times TM \rightarrow M$ by using metrics varying along S , equal to g_I near the boundary components $I \subset \partial S$. Restricting to a sufficiently small neighbourhood $\mathcal{U} \subset TM$ of the zero section, we can rephrase this as $\exp(z, \xi) = \exp^0(\xi + Q(z, \xi))$ in terms of a standard exponential map $\exp^0 : TM \rightarrow M$ using a fixed metric and a quadratic correction $Q : S \times \mathcal{U} \rightarrow TM$ satisfying $Q(\cdot, 0) = 0$ and $dQ(\cdot, 0) = 0$. In fact, the quadratic correction is explicitly given by $Q(z, \xi \in T_p M \cap \mathcal{U}) := (\exp_p^0)^{-1}(\exp(z, \xi)) - \xi$. To satisfy the second requirement we define the parallel transport $\Phi_u(\xi)$ by the usual complex linear connection constructed from Levi-Civita connections of fixed metrics, but we do parallel transport along the paths $s \mapsto \exp_{u(z)}(z, s\xi(z)) = \exp_u^0(s\xi + Q(s\xi))$. Note that the derivative at $s = 0$ of these paths still is ξ , independent of the quadratic correction.

The operator σ_u is well-defined for any $p > 2$ as a map from the $W^{1,p}$ -closure of $\Omega^0(S, u^*TM)$ to the L^p -closure of $\Omega^{0,1}(S, u^*TM)$. We denote by $D_u := d\sigma_u(0)$ its derivative at zero. The linearized operator constructed in this way takes the same form as in [6] – it is in fact independent of the choice of quadratic correction. So it takes the form $D_u = D_{E_u, \mathcal{F}_u}$ of a real Cauchy-Riemann operator as discussed in the linear theory above. When u is holomorphic, the operator D_u is the linearized operator of (a) – defined independently from the choice of connection and metric.

2) If the tuple of Lagrangians $(L_I)_{I \in \pi_0(\partial S)}$ is monotone in the sense of [19], then elements $u \in \mathcal{M}_S(X^-, X^+)$ (and more generally maps u as in (1)) satisfy the energy-index relation

$$(3) \quad 2E_{K_S}(u) = \tau \cdot \text{Ind}(D_u) + c(X^-, X^+).$$

The identity is seen by fixing one element $v_0 \in \mathcal{M}_S(X^-, X^+)$ but interpreting it as map $v_0 : S^- \rightarrow M$ defined on the surface $S^- = (S, -j)$ with reversed orientation. Now given any $u \in \mathcal{M}_S(X^-, X^+)$ we glue it with v_0 (by reparametrization that makes them constant near the ends) to a map $w = u \# v_0$ on the compact doubled surface $S \# S^-$, in which each end of S is glued to the corresponding end of S^- . Since $K_S|_{\partial S} = 0$ and $K_S \circ u = K_S \circ v_0$ in the limit on the strip-like ends, the Hamiltonian terms for u and v_0 cancel and we have

$$\int_{S \# S^-} w^* \omega = \int_S u^* \omega + \int_{S^-} v_0^* \omega = E_{K_S}(u) + E_{K_S}(v_0).$$

On the other hand, a linear gluing theorem as in [12, Section 3.2] provides

$$\text{Ind}(D_u) + \text{Ind}(D_{v_0}) = \text{Ind}(D_w) = I(w^*TM, (w^*TL_I)_{I \in \pi_0(\partial(S \# S^-))}) + \frac{\dim M}{2} \chi(S \# (-S))$$

Here the equality to the Maslov index follows from (2). Finally, we have $2 \int_{S \# S^-} w^* \omega = \tau I(w^*TM, (w^*TL_I)_{I \in \pi_0(\partial(S \# S^-))})$ by the monotonicity assumption. This proves (3) with $c(X^-, X^+) = \tau \cdot \text{Ind}(D_{v_0}) - \tau \frac{\dim M}{2} \chi(S \# S^-) - 2E_{K_S}(v_0)$.

- 3) If the Lagrangians $(L_I)_{I \in \pi_0(\partial S)}$ are all oriented, then the index $\text{Ind}(D_u)$ of a map u as in (1) is determined mod 2 by the surface S and limit conditions X^-, X^+ . This is since in the above index formula a change of u with fixed ends is only reflected in a change of the topological index $I(w^*TM, (w^*TL_I)_{I \in \pi_0(\partial S \# S^-)})$. This index however is always even since by (L2) the totally real subbundles w^*TL_I are oriented.

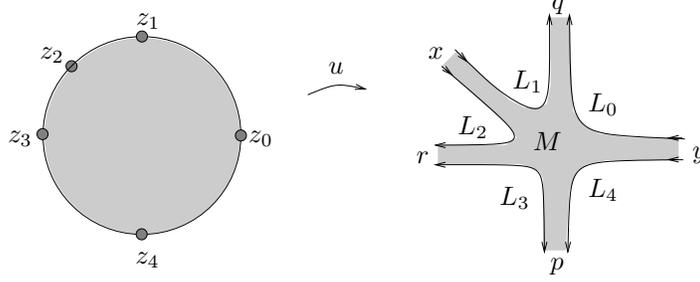

Figure 1. A holomorphic curve $u \in \mathcal{M}_S((x, y), (p, q, r))$ for a surface S with ends $\mathcal{E}_- = \{2, 0\}$ and $\mathcal{E}_+ = \{4, 1, 3\}$

Theorem 2.3. *Suppose that $(L_I)_{I \in \pi_0(\partial S)}$ is a monotone tuple of Lagrangian submanifolds satisfying (L1-2) and (M1-2), and that regular perturbation data (H_e, J_e) are chosen for each end $e \in \mathcal{E}$. Then for any $H_S \in \text{Ham}(S; (H_e)_{e \in \mathcal{E}})$ there exists a dense comeagre⁴ subset $\mathcal{J}^{\text{reg}}(S; (J_e)_{e \in \mathcal{E}}; H_S) \subset \mathcal{J}(S; (J_e)_{e \in \mathcal{E}})$ such that for any tuple $(X^-, X^+) \in \mathcal{I}_- \times \mathcal{I}_+$ the following holds.*

- $\mathcal{M}_S(X^-, X^+)$ is a smooth manifold.
- The zero dimensional component $\mathcal{M}_S(X^-, X^+)_0$ is finite.
- The one-dimensional component $\mathcal{M}_S(X^-, X^+)_1$ has a compactification as a one-manifold with boundary

$$\begin{aligned} \partial \overline{\mathcal{M}_S(X^-, X^+)_1} \cong & \bigcup_{e \in \mathcal{E}_-, y \in \mathcal{I}(L_e, L_{e-1})} \mathcal{M}(x_e^-, y)_0 \times \mathcal{M}_S(X^-|_{x_e^- \rightarrow y}, X^+)_0 \\ & \cup \bigcup_{e \in \mathcal{E}_+, y \in \mathcal{I}(L_{e-1}, L_e)} \mathcal{M}_S(X^-, X^+|_{x_e^+ \rightarrow y})_0 \times \mathcal{M}(y, x_e^+)_0, \end{aligned}$$

where the tuple $X|_{x_e \rightarrow y}$ is X with the intersection point x_e replaced by y .

- If $(L_I)_{I \in \pi_0(\partial S)}$ is relatively spin then there exist a coherent set of orientations ϵ on the zero and one-dimensional moduli spaces so that the inclusion of the boundary in (c) has the signs $(-1)^{\sum_{f < e} |x_f^-|}$ (for incoming trajectories) and $-(-1)^{\sum_{f < e} |x_f^+|}$ (for outgoing trajectories.)

The proof is similar to the regularity and compactness theorems [7] in monotone Floer theory; see [15] for the exact case. In the moduli spaces of dimension 0 and 1 the bubbling of spheres and disks is ruled out by monotonicity and (L2). The orientations are defined in [15] or [20]. We can thus define

$$C\Phi_S : \bigotimes_{e \in \mathcal{E}_-} CF(L_e, L_{e-1}) \rightarrow \bigotimes_{e \in \mathcal{E}_+} CF(L_{e-1}, L_e)$$

by

$$C\Phi_S \left(\bigotimes_{e \in \mathcal{E}_-} \langle x_e^- \rangle \right) := \sum_{X^+ \in \mathcal{I}_+} \left(\sum_{u \in \mathcal{M}_S(X^-, X^+)_0} \epsilon(u) \right) \bigotimes_{e \in \mathcal{E}_+} \langle x_e^+ \rangle.$$

⁴A subset of a topological space is *comeagre* if it is the intersection of countably many open dense subsets. In a Baire space, this intersection is still dense, and the space of smooth almost complex structures is naturally a Baire space. For more details, see the proof of Theorem 5.2.4 in [19].

By items (c),(d), the maps $C\Phi_S$ are chain maps and so descend to a map of Floer cohomologies

$$(4) \quad \Phi_S : \bigotimes_{e \in \mathcal{E}_-} HF(L_e, L_{e-1}) \rightarrow \bigotimes_{e \in \mathcal{E}_+} HF(L_{e-1}, L_e).$$

In order for the Floer cohomologies to be well defined, we have to assume in addition that all Lagrangians in $(L_I)_{I \in \pi_0(\partial S)}$ satisfy (L3). Floer's argument using parametrized moduli spaces carries over to this case to show that Φ_S is independent of the choice of perturbation data, complex structure j on S , and the strip-like ends. We sketch this argument in Section 4 for the more general quilted case.

Remark 2.4. Recall that M is equipped with an N -fold Maslov covering and each Lagrangian submanifold $L_I \subset M$ is graded. Suppose that S is connected. Then the effect of the relative invariant Φ_S on the grading is by a shift in degree of

$$|\Phi_S| = \frac{1}{2} \dim M (\#\mathcal{E}_+ - \chi(\bar{S})) \pmod{N}.$$

That is, the coefficient of $C\Phi_S(\bigotimes_{e \in \mathcal{E}_-} \langle x_e^- \rangle)$ in front of $\bigotimes_{e \in \mathcal{E}_+} \langle x_e^+ \rangle$ is zero unless the degrees $|x_e^-| = d(\sigma_{L_e}^N(x_e^-), \sigma_{L_{e-1}}^N(x_{e-1}^-))$ and $|x_e^+| = d(\sigma_{L_{e-1}}^N(x_{e-1}^+), \sigma_{L_e}^N(x_e^+))$ satisfy

$$\sum_{e \in \mathcal{E}_+} |x_e^+| - \sum_{e \in \mathcal{E}_-} |x_e^-| = \frac{1}{2} \dim M (\#\mathcal{E}_+ - \chi(\bar{S})) \pmod{N}.$$

Here $\#\mathcal{E}_+$ is the number of outgoing ends of S . So, for example, Φ_S preserves the degree if S is a disk with one outgoing end and any number of incoming ends.

To check the degree identity fix paths $\tilde{\Lambda}_e : [0, 1] \rightarrow \text{Lag}^N(T_{x_e}M)$ from $\sigma_{L_{e-1}}^N(x_{e-1})$ to $\sigma_{L_e}^N(x_e)$ for each end $e \in \mathcal{E}(S)$, and denote their projections by $\Lambda_e : [0, 1] \rightarrow T_{x_e}M$. Let $D_{T_{x_e}M, \Lambda_e}$ be the Cauchy-Riemann operator in $T_{x_e}M$ on the disk with one incoming strip-like end and with boundary conditions Λ_e . Then (see [19]) we have

$$|x_e^\pm| = \text{Ind}(D_{T_{x_e}M, \Lambda_e^\pm}), \quad e \in \mathcal{E}_\pm$$

with the reversed path $\tilde{\Lambda}_e^{-1}$ from $\sigma_{L_e}^N(x_e)$ to $\sigma_{L_{e-1}}^N(x_{e-1})$ in case $e \in \mathcal{E}_-$. In this case we have

$$\text{Ind}(D_{T_{x_e}M, \Lambda_e^{-1}}) + \text{Ind}(D_{T_{x_e}M, \Lambda_e}) = \frac{1}{2} \dim M \pmod{N}$$

since gluing the two disks gives rise to a Cauchy-Riemann operator on the disk with boundary conditions given by the loop $\Lambda_e^{-1} \# \Lambda_e$, which lifts to a loop in $\text{Lag}^N(T_{x_e}M)$ and hence has Maslov index $0 \pmod{N}$. Now consider an isolated solution $u \in \mathcal{M}_S(X^-, X^+)_0$. For each end $e \in \mathcal{E}(S)$ we can glue the operator $D_{T_{x_e}M, \Lambda_e^{-1}}$ on the disk to the linearized Cauchy-Riemann operator $D_{u^*TM, (u^*TL_I)_{I \in \pi_0(\partial S)}}$ on the surface S . This gives rise to a Cauchy-Riemann operator on the compact surface \bar{S} with boundary conditions given by Lagrangian subbundles (given by u^*TL_I for compact boundary components $I \subset \partial S$ and composed of u^*TL_e and Λ_e^{-1} for noncompact components I_e) that lift to loops in $\text{Lag}^N(M)$ (given by $\sigma_{L_I} \circ u|_I$ resp. composed of $\sigma_{L_e} \circ u|_{I_e}$ and $(\tilde{\Lambda}_e)^{-1}$). In a trivialization of u^*TM their Maslov indices are hence divisible by N , and so the index of the glued Cauchy-Riemann operator is

$$\begin{aligned} \frac{1}{2} \dim M \cdot \chi(\bar{S}) &= \text{Ind}(D_{u^*TM, (u^*TL_I)_{I \in \pi_0(\partial S)}}) + \sum_{e \in \mathcal{E}(S)} \text{Ind}(D_{TM, \Lambda_e^{-1}}) \pmod{N} \\ &= 0 + \sum_{e \in \mathcal{E}_+(S)} (\frac{1}{2} \dim M - |x_e^+|) + \sum_{e \in \mathcal{E}_-(S)} |x_e^-| \pmod{N}. \end{aligned}$$

Example 2.5 (Strip Example). If S_{\parallel} is the strip $\mathbb{R} \times [0, 1]$ (i.e. the disk with one incoming and one outgoing puncture) then we can choose perturbation data that preserve the \mathbb{R} -invariance of the holomorphic curves. Then any nonconstant solution comes in a 1-dimensional family and hence $\Phi_{S_{\parallel}}$ is generated by the constant solutions. The same holds for the disks S_{\cap} and S_{\cup} with two incoming

resp. two outgoing ends. With our choice of coherent orientations, see [20], we obtain (as map of degree 0)

$$\Phi_{\parallel} := \Phi_{S_{\parallel}} = \text{Id} : HF(L_0, L_1) \rightarrow HF(L_0, L_1).$$

The disks S_{\cap} and S_{\cup} give rise to maps of degree $-\frac{1}{2} \dim M$ and $\frac{1}{2} \dim M$ respectively,

$$(5) \quad \Phi_{\cap} := \Phi_{S_{\cap}} : HF(L_0, L_1) \otimes HF(L_1, L_0) \rightarrow \mathbb{Z},$$

$$(6) \quad \Phi_{\cup} := \Phi_{S_{\cup}} : \mathbb{Z} \rightarrow HF(L_0, L_1) \otimes HF(L_1, L_0).$$

We write $\langle x_i \rangle_{01} \in CF(L_0, L_1)$ resp. $\langle x_i \rangle_{10} \in CF(L_1, L_0)$ for the generators corresponding to the intersection points $\mathcal{I}(L_0, L_1) \cong \mathcal{I}(L_1, L_0) = \{x_i \mid i = 1, \dots, N\}$. Then, on the chain level, the maps are given by $C\Phi_{\parallel} : \langle x_i \rangle_{01} \mapsto \langle x_i \rangle_{01}$ and

$$C\Phi_{\cap} : \langle x_i \rangle_{01} \otimes \langle x_j \rangle_{10} \mapsto (-1)^{|\langle x_i \rangle_{01}|} \epsilon_i \delta_{ij}, \quad C\Phi_{\cup} : 1 \mapsto \sum_i \epsilon_i \langle x_i \rangle_{01} \otimes \langle x_i \rangle_{10}$$

for some signs $\epsilon_1, \dots, \epsilon_N \in \{\pm 1\}$.⁵ Here the degrees are related by $|\langle x_i \rangle_{01}| + |\langle x_i \rangle_{10}| = \frac{1}{2} \dim M$ as in Remark 2.4.

The relative invariants satisfy a tensor product law for disjoint union. A careful construction of the orientations (see [20]) leads to the following convention.

Lemma 2.6. *Let S_1, S_2 be surfaces with strip like ends and let $S_1 \sqcup S_2$ be the disjoint union, with ordering of boundary components and incoming and outgoing ends induced by the corresponding orderings on S_1, S_2 . Then*

$$\Phi_{S_1 \sqcup S_2} = \Phi_{S_1} \otimes \Phi_{S_2},$$

where the graded tensor product is defined by

$$(7) \quad (\Phi_{S_1} \otimes \Phi_{S_2})(\langle X_1^- \rangle \otimes \langle X_2^- \rangle) = (-1)^{|\Phi_{S_2}| |X_1^-|} \Phi_{S_1}(\langle X_1^- \rangle) \Phi_{S_2}(\langle X_2^- \rangle).$$

Moreover, the relative invariants satisfy a composition law for gluing along ends. Suppose that $e_+ \in \mathcal{E}_+(S)$ and $e_- \in \mathcal{E}_-(S)$ are outgoing resp. incoming ends of S such that the Lagrangians agree, $L_{e_+ - 1} = L_{e_-}$ and $L_{e_+} = L_{e_- - 1}$. Then we can algebraically define the trace of Φ_S at (e_-, e_+)

$$(8) \quad \begin{aligned} \text{Tr}_{e_-, e_+}(\Phi_S) : & \bigotimes_{e \in \mathcal{E}_-(S) \setminus \{e_-\}} HF(L_e, L_{e-1}) \rightarrow \bigotimes_{e \in \mathcal{E}_+(S) \setminus \{e_+\}} HF(L_{e-1}, L_e) \\ & \text{Tr}_{e_-, e_+}(\Phi_S) := (\text{Id}^{\mathcal{E}_+ \setminus \{e_+\}} \otimes \Phi_{\cap}^{e_+, e_0}) \circ (\Psi_{e_+} \otimes \text{Id}^{e_0}) \circ (\Phi_S \otimes \text{Id}^{e_0}) \\ & \quad \circ (\Psi_{e_-} \otimes \text{Id}^{e_0}) \circ (\text{Id}^{\mathcal{E}_- \setminus \{e_-\}} \otimes \Phi_{\cup}^{e_-, e_0}), \end{aligned}$$

where

- a) superscripts indicate the ends (and associated Floer cohomology groups) that the maps act on,
- b) e_0 is an additional end associated to the Floer cohomology group $HF(L_{e_- - 1}, L_{e_-}) = HF(L_{e_+}, L_{e_+ - 1})$,
- c) $\Psi_{e_{\pm}}$ are the permutations of the factors in the graded tensor product needed to make the compositions well-defined,

$$\begin{aligned} \Psi_{e_-} : & \left(\bigotimes_{e \in \mathcal{E}_- \setminus \{e_-\}} \langle x_e \rangle \right) \otimes \langle x_{e_-} \rangle \mapsto (-1)^{|x_{e_-}| \sum_{\mathcal{E}_- \ni f > e_-} |x_f|} \bigotimes_{e \in \mathcal{E}_-} \langle x_e \rangle, \\ \Psi_{e_+} : & \bigotimes_{e \in \mathcal{E}_+} \langle x_e \rangle \mapsto (-1)^{|x_{e_+}| \sum_{\mathcal{E}_+ \ni f > e_+} |x_f|} \left(\bigotimes_{e \in \mathcal{E}_+ \setminus \{e_+\}} \langle x_e \rangle \right) \otimes \langle x_{e_+} \rangle. \end{aligned}$$

⁵For a fixed ordered pair (L_0, L_1) one can refine the choice of coherent orientations such that the signs in Φ_{\cap} are $\epsilon_i = +1$. For the reversed pair (L_1, L_0) this convention yields the same signs $\epsilon'_i = +1$ in Φ_{\cap} if $\frac{1}{2} \dim M$ is odd, but they vary, $\epsilon'_i = (-1)^{|\langle x_i \rangle_{10}|}$, if $\frac{1}{2} \dim M$ even. (In the latter case the signs in Φ_{\cup} are all positive.)

Note that the trace does not depend on the choice of the signs ϵ_i in (5). On the other hand, let $\#_{e_+}^{e_-}(S)$ denote the surface obtained by gluing together the ends e_\pm , and choose an ordering of the boundary components and strip-like ends. (There is no canonical choice for this general gluing procedure.) The glued surface $\#_{e_+}^{e_-}(S)$ can be written as the “geometric trace”

$$(S_{\parallel}^{\mathcal{E}_+ \setminus \{e_+\}} \sqcup S_{\cap}^{e_+, e_0}) \# (S_{\Psi_{e_+}} \sqcup S_{\parallel}^{e_0}) \# (S \sqcup S_{\parallel}^{e_0}) \# (S_{\Psi_{e_-}} \sqcup S_{\parallel}^{e_0}) \# (S_{\parallel}^{\mathcal{E}_- \setminus \{e_-\}} \sqcup S_{\cup}^{e_-, e_0}),$$

where $S_0 \# S_1$ denotes the gluing of all incoming ends of S_0 to the outgoing ends of S_1 (which must be identical and in the same order). Here superscripts indicate the indexing of the ends of the surfaces, so e.g. $S_{\parallel}^{\mathcal{E}_+ \setminus \{e_+\}}$ is a product of strips $\mathbb{R} \times [0, 1]$ with both incoming and outgoing ends indexed by $\mathcal{E}_+ \setminus \{e_+\}$. The surfaces $S_{\Psi_{e_\pm}}$ are the products of strips with incoming ends indexed by $(\mathcal{E}_- \setminus \{e_-\}, e_-)$ resp. \mathcal{E}_+ and outgoing ends indexed by \mathcal{E}_+ resp. $(\mathcal{E}_+ \setminus \{e_+\}, e_+)$ (in the order indicated). The relative invariants associated to the surfaces in this geometric trace are exactly the ones that we compose in the definition (8) of the algebraic trace. In fact, the standard Floer gluing construction implies the following analogue of the gluing formula [14, 2.30] in the exact case.

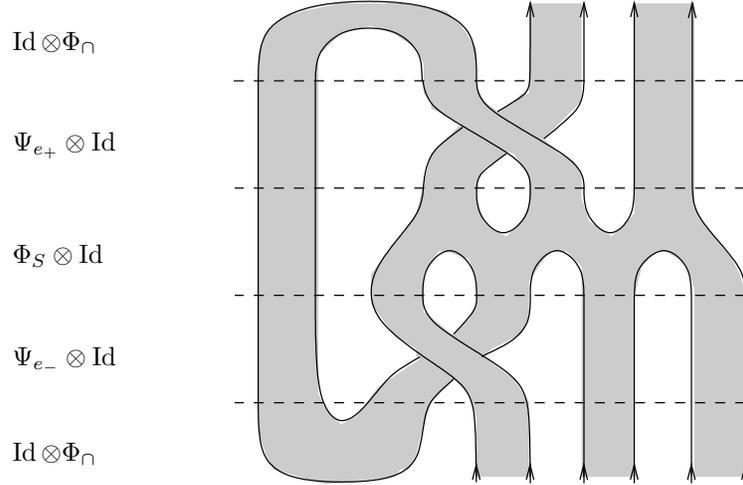

Figure 2. Gluing example for a connected surface S

Theorem 2.7 (Gluing Theorem). *Let S be a surface with strip-like ends and $(L_e)_{e \in \mathcal{E}(S)}$ Lagrangians as in Theorem 2.3, satisfying in addition (L3) and (G1-2). Suppose that $e_\pm \in \mathcal{E}_\pm(S)$ such that $L_{e_+ - 1} = L_{e_-}$ and $L_{e_+} = L_{e_- - 1}$. Then*

$$\Phi_{\#_{e_+}^{e_-}(S)} = (\epsilon_{S, \#_{e_+}^{e_-}(S)})^{\dim(M)/2} \text{Tr}_{e_-, e_+}(\Phi_S),$$

where $\epsilon_{S, \#_{e_+}^{e_-}(S)} = \pm 1$ is a universal sign depending on the surfaces, that is, the ordering of boundary components etc.

Unfortunately it seems one cannot make the sign more precise, since there is no canonical convention for ordering the boundary components etc. of the glued surface.

Sketch of Proof: By Theorem 4.1, the relative invariant for the geometric trace can be computed using a surface with long necks between the glued surfaces. Solutions (of both the linear and non-linear equation) on this surface are in one-to-one correspondence with pairs of solutions on the two separate surfaces; counting the latter exactly corresponds to composition. The one-to-one correspondence is proven by an implicit function theorem (using the fact that the linearized operator as well as its adjoint are surjective in the index 0 case) and a compactness result (using

monotonicity to exclude bubbling). Details for the analogous closed case can be found in [12, Chapter 5.4]. Universality of the gluing sign for the case of simultaneous gluing of all ends is proved in [20]. By definition, our algebraic trace is the composition of the relative invariants of $S_{\parallel}^{\mathcal{E}_+ \setminus \{e_+\}} \sqcup S_{\cap}^{e_+, e_0}$, $S_{\Psi_{e_+}} \sqcup S_{\parallel}^{e_0}$, $S \sqcup S_{\parallel}^{e_0}$, $S_{\Psi_{e_-}} \sqcup S_{\parallel}^{e_0}$, and $S_{\parallel}^{\mathcal{E}_- \setminus \{e_-\}} \sqcup S_{\cup}^{e_-, e_0}$, see Lemma 2.6. \square

In [20] we determine more explicitly the gluing signs in two special cases: Gluing a surface with one outgoing end to the first incoming end of another surface, and gluing the ends of a surface with single incoming and outgoing ends (which lie on the same boundary component).

Theorem 2.8. *If S is a disjoint union $S = S_0 \sqcup S_1$ with $z_{e_-} \in S_0$, $z_{e_+} \in S_1$, and if S_1 has a single outgoing end $\mathcal{E}_+(S_1) = \{e_+\}$, we define canonical orderings as follows: Suppose that e_- is the last incoming end of S_0 and the boundary components containing z_{e_-} resp. z_{e_+} are last in S_0 resp. first in S_1 . Then we order the boundary components and ends of the glued surface $(S_0) \#_{e_+}^{e_-}(S_1) := \#_{e_+}^{e_-}(S_0 \sqcup S_1)$ by appending the additional boundaries and incoming ends of S_1 to the ordering for S_0 . With these conventions we have*

$$\Phi_{(S_0) \#_{e_+}^{e_-}(S_1)} = \epsilon \cdot \Phi_{S_0} \circ (1^{\mathcal{E}_-(S_0) \setminus \{e_-\}} \otimes \Phi_{S_1}),$$

where $\epsilon = 1$ if $n = \frac{1}{2} \dim M$ is even or the number b_1 of boundary components of \overline{S}_1 is odd, and in general

$$\epsilon = (-1)^{n(b_1+1) \sum_{e \in \mathcal{E}_-(S_0) \setminus \{e_-\}} (n - |x_e|)}.$$

In our concrete situations the surfaces will usually have one boundary component, $b_1 = 1$, and one outgoing end, hence the gluing sign will be $\epsilon = +1$.

Theorem 2.9. *If S is connected with exactly one incoming and one outgoing end $\mathcal{E} = \{e_+, e_-\}$ lying on the same, first boundary component, we define canonical orderings as follows: The glued surface $\#_{e_+}^{e_-}(S)$ has no further ends but two new compact boundary components, which we order by taking the one labelled L^1 first and that labelled L^2 second, where (L^1, L^2) denote the ordered boundary conditions at the outgoing end e_+ . (Then the ordered boundary conditions at e_- are (L^2, L^1) .) After these new components we order the remaining boundary components in the order induced by S . With that convention we have*

$$(9) \quad \Phi_{\#_{e_+}^{e_-}(S)} : 1 \mapsto \text{Tr}(\Phi_S) = \sum_i (-1)^{|x_i|} \langle C\Phi_S(\langle x_i \rangle), \langle x_i \rangle \rangle,$$

the (graded) sum over the $\langle x_i \rangle$ coefficients of $C\Phi_S(\langle x_i \rangle)$.

Example 2.10. We compute the invariants for closed surfaces as follows:

- (Disk) If S is the disk with boundary condition L , then Φ_S is the number of isolated perturbed J -holomorphic disks with boundary in L . Because of the monotonicity assumption, and since we do not quotient out by automorphisms of the disk, each component of the moduli space of such disks has at least the dimension of L , hence $\Phi_S = 0$.
- (Annulus) Let $A = \#S_{\parallel}$ denote the annulus, obtained by gluing along the two ends of the infinite strip $S_{\parallel} = \mathbb{R} \times [0, 1]$ with boundary conditions L_0 and L_1 . Let the boundary components be ordered like (L_0, L_1) , as in Theorem 2.9. Then the gluing formula produces

$$\Phi_A = \text{Tr}(\text{Id}) = \text{rank } HF^{\text{even}}(L_0, L_1) - \text{rank } HF^{\text{odd}}(L_0, L_1).$$

The same result can be obtained by decomposing the annulus into cup and cap and computing the universal sign to $\Phi_A = \Phi_{\cap} \circ \Phi_{\cup}$.

- (Sphere with holes) Let S denote the sphere with $g + 1$ disks removed and boundary condition L over each component. S can be obtained by gluing together $g - 1$ copies of the surface S_0 , which is obtained by removing a disk from the strip $\mathbb{R} \times [0, 1]$; see Figure 3. The latter defines an automorphism Φ_{S_0} on $HF(L, L)$, and the gluing formulas give

$$\Phi_S = \text{Tr}(\Phi_{S_0}^{g-1}) = \sum (-1)^{|x_i|} \langle \Phi_{S_0}^{g-1}(\langle x_i \rangle), \langle x_i \rangle \rangle.$$

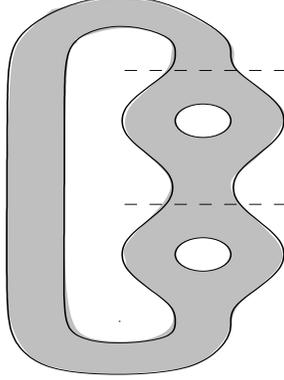

Figure 3. Gluing copies of S_0

Remark 2.11. If M is compact, then one can also allow surfaces to have incoming or outgoing cylindrical ends, equipped with a periodic Hamiltonian perturbation. In this case the relative invariant acts on the product of Floer cohomology groups with a number of copies of the cylindrical Floer cohomology $HF(\text{Id})$, isomorphic to the quantum cohomology $QH(M)$ of M . For instance, a disk with one puncture in the interior gives rise to a canonical element $\phi_L \in HF(\text{Id})$. Splitting the annulus into two half-cylinders glued at a cylindrical end gives rise to the identity

$$\text{rank } HF^{\text{even}}(L_0, L_1) - \text{rank } HF^{\text{odd}}(L_0, L_1) = \langle \phi_{L_0}, \phi_{L_1} \rangle_{HF(\text{Id})}.$$

By considering a disk with one interior and one boundary puncture one obtains the open-closed map $HF(L, L) \rightarrow HF(\text{Id})$, which is discussed by Albers [2, Theorem 3.1].

3. Invariants for quilted surfaces

Quilted surfaces are obtained from a collection of surfaces with strip-like ends by “sewing together” certain pairs of boundary components. We give a formal definition below, again restricting to strip-like ends, i.e. punctures on the boundary. One could in addition allow cylindrical ends by adding punctures in the interior of the surface, see Remark 3.12.

Definition 3.1. A *quilted surface* \underline{S} with strip-like ends consists of the following data:

- A collection $\underline{S} = (S_k)_{k=1, \dots, m}$ of *patches*, that is surfaces with strip-like ends as in Definition 2.1 (a)-(c). In particular, each S_k carries a complex structures j_k and has strip-like ends $(\epsilon_{k,e})_{e \in \mathcal{E}(S_k)}$ of widths $\delta_{k,e} > 0$ near marked points $\lim_{s \rightarrow \pm\infty} \epsilon_{k,e}(s, t) = z_{k,e} \in \partial \bar{S}_k$. We denote by $I_{k,e} \subset \partial S_k$ the noncompact boundary component between $z_{k,e-1}$ and $z_{k,e}$.
- A collection $\mathcal{S} = \{(k_\sigma, I_\sigma), (k'_\sigma, I'_\sigma)\}_{\sigma \in \mathcal{S}}$ of *seams*, that is pairwise disjoint 2-element subsets

$$\sigma \subset \bigcup_{k=1}^m \{k\} \times \pi_0(\partial S_k),$$

and for each $\sigma \in \mathcal{S}$, a diffeomorphism of boundary components

$$\varphi_\sigma : \partial S_{k_\sigma} \ni I_\sigma \xrightarrow{\sim} I'_\sigma \subset \partial S_{k'_\sigma}$$

that is

- real analytic*: Every $z \in I_\sigma$ has an open neighbourhood $\mathcal{U} \subset S_{k_\sigma}$ such that $\varphi_\sigma|_{\mathcal{U} \cap I_\sigma}$ extends to an embedding $\psi_z : \mathcal{U} \rightarrow S_{k'_\sigma}$ with $\psi_z^* j_{k'_\sigma} = -j_{k_\sigma}$. In particular, this forces φ_σ to reverse the orientation on the boundary components. ⁶

⁶In order to drop the real analyticity condition, one would have to extend each part of the analysis for pseudoholomorphic curves with Lagrangian boundary conditions (e.g. linear theory, nonlinear regularity, and removal of singularities) to the case of maps $(u_0, u_1) : (\mathbb{H}^2, \partial \mathbb{H}^2) \rightarrow (M_0 \times M_1, L_{01})$ on the half space with Lagrangian boundary

- ii) *compatible with strip-like ends* : If I_σ (and hence I'_σ) is noncompact, i.e. lie between marked points, $I_\sigma = I_{k_\sigma, e_\sigma}$ and $I'_\sigma = I_{k'_\sigma, e'_\sigma}$, then we require that φ_σ matches up the end e_σ with $e'_\sigma - 1$ and the end $e_\sigma - 1$ with e'_σ . That is $\epsilon_{k'_\sigma, e'_\sigma}^{-1} \circ \varphi_\sigma \circ \epsilon_{k_\sigma, e_\sigma - 1}$ maps $(s, \delta_{k_\sigma, e_\sigma - 1}) \mapsto (s, 0)$ if both ends are incoming, or it maps $(s, 0) \mapsto (s, \delta_{k'_\sigma, e'_\sigma})$ if both ends are outgoing. We disallow matching of an incoming with an outgoing end, and the condition on the other pair of ends is analogous, see Figure 4.
- c) As a consequence of (a) and (b) we obtain a set of remaining boundary components $I_b \subset \partial S_{k_b}$ that are not identified with another boundary component of $\underline{\mathcal{S}}$. These *true boundary components* of $\underline{\mathcal{S}}$ are indexed by

$$\mathcal{B} = ((k_b, I_b))_{b \in \mathcal{B}} := \bigcup_{k=1}^m \{k\} \times \pi_0(\partial S_k) \setminus \bigcup_{\sigma \in \mathcal{S}} \sigma.$$

Moreover, we can read off the *quilted ends* $\underline{e} \in \mathcal{E}(\underline{\mathcal{S}}) = \mathcal{E}_-(\underline{\mathcal{S}}) \sqcup \mathcal{E}_+(\underline{\mathcal{S}})$ consisting of a maximal sequence $\underline{e} = (k_i, e_i)_{i=1, \dots, n_{\underline{e}}}$ of ends of patches with boundaries $\epsilon_{k_i, e_i}(\cdot, \delta_{k_i, e_i}) \cong \epsilon_{k_{i+1}, e_{i+1}}(\cdot, 0)$ identified via some seam ϕ_{σ_i} . This end sequence could be cyclic, i.e. with an additional identification $\epsilon_{k_n, e_n}(\cdot, \delta_{k_n, e_n}) \cong \epsilon_{k_1, e_1}(\cdot, 0)$ via some seam ϕ_{σ_n} . Otherwise the end sequence is noncyclic, i.e. $\epsilon_{k_1, e_1}(\cdot, 0) \in I_{b_0}$ and $\epsilon_{k_n, e_n}(\cdot, \delta_{k_n, e_n}) \in I_{b_n}$ take value in some true boundary components $b_0, b_n \in \mathcal{B}$. In both cases, the ends ϵ_{k_i, e_i} of patches in one quilted end \underline{e} are either all incoming, $e_i \in \mathcal{E}_-(S_{k_i})$, in which case we call the quilted end incoming, $\underline{e} \in \mathcal{E}_-(\underline{\mathcal{S}})$, or they are all outgoing, $e_i \in \mathcal{E}_+(S_{k_i})$, in which case we call the quilted end outgoing, $\underline{e} \in \mathcal{E}_+(\underline{\mathcal{S}})$.

- d) Orderings of the patches and of the boundary components of each \bar{S}_k as in Definition 2.1 (d). There is no ordering of ends of single patches but orderings $\mathcal{E}_-(\underline{\mathcal{S}}) = (\underline{e}_1^-, \dots, \underline{e}_{N_-}^-(\underline{\mathcal{S}}))$ and $\mathcal{E}_+(\underline{\mathcal{S}}) = (\underline{e}_1^+, \dots, \underline{e}_{N_+}^+(\underline{\mathcal{S}}))$ of the quilted ends. Moreover, we fix an ordering $\underline{e} = ((k_1, e_1), \dots, (k_{n_{\underline{e}}}, e_{n_{\underline{e}}}))$ of strip-like ends for each quilted end \underline{e} . For noncyclic ends, this ordering is determined by the order of seams as in (c). For cyclic ends, we need to fix a first strip-like end (k_1, e_1) to fix this ordering.

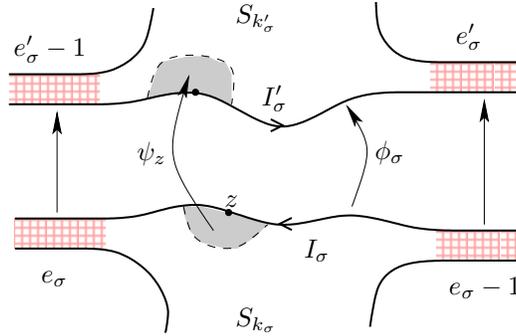

Figure 4. Totally real seam compatible with strip-like ends

A picture of a quilt is shown in Figure 5. Ends at the top resp. bottom of a picture will always indicate outgoing resp. incoming ends. The alternative picture is that in which the ends are neighbourhoods of punctures and we indicate by arrows whether the ends are outgoing or incoming. Here we draw the quilted surface as a disc, but in general this could be a more general surface. Also, the complex structures on the patches are not necessarily induced by the embedding into the plane, as

conditions such that each component u_i is pseudoholomorphic with respect to a different complex structure j_i on \mathbb{H}^2 , that is, $J_i \circ du_i = du_i \circ j_i$ for $i = 0, 1$. This seems doable, but would require a lot of hard technical work. However, none of this work is necessary if one restricts to real analytic seams. In that case, the only fundamental difficulty is resolved by Lemma 3.4 establishing homotopies between quilted surfaces of the same combinatorial type.

drawn. Ignoring complex structures, the two views of the quilted surface in Figure 5 are diffeomorphic. In this example the end sequences are $(2, 0), (1, 0)$ and $(2, 1)$ for the incoming ends (at the bottom), and $(2, 2), (3, 0), (2, 3), (1, 1)$ for the outgoing end (at the top). (Our only choice here is which marked point on the boundary circles of S_i to label by 0.)

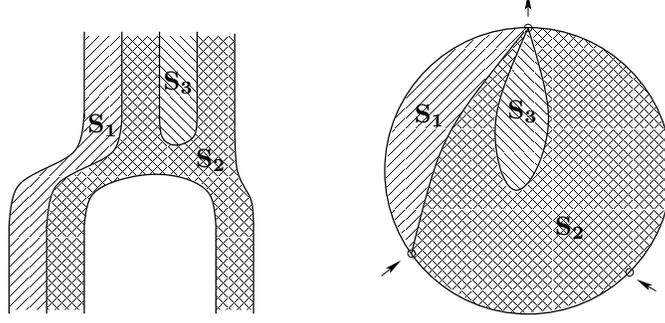

Figure 5. Two views of a quilted surface

- Remark 3.2.**
- a) Every compact boundary component $S^1 \cong I \subset \partial S_k$ of a surface with strip-like ends has a uniformizing neighbourhood $U_I \subset \partial S_k$ such that $(U_I, j_k) \cong (S^1 \times [0, \epsilon), i)$, where $S^1 \cong \mathbb{R}/\mathbb{Z}$ and i denotes the standard complex structure on $\mathbb{R} \times \mathbb{R} \cong \mathbb{C}$. Due to the strip-like ends, the same holds for noncompact boundary components $\mathbb{R} \cong I \subset \partial S_k$, where $(U_I, j_k) \cong (\mathbb{R} \times [0, \epsilon), i)$.
 - b) Seams that are compatible with the strip-like ends are automatically real analytic on these ends since φ_σ extends to $(s, \delta_{k,e} - t) \mapsto (s, t)$ resp. $(s, t) \mapsto (s, \delta_{k',e'} - t)$.
 - c) In the uniformizing neighbourhoods of (a), the condition that a seam $\varphi_\sigma : I_\sigma \rightarrow I'_\sigma$ be real analytic is equivalent to $\varphi_\sigma : \mathbb{R} \rightarrow \mathbb{R}$ (resp. $\varphi_\sigma : S^1 \rightarrow S^1$ in the compact case) being real analytic. As a consequence, the extensions ψ_z match up to an embedding $\psi_\sigma : U_{I_\sigma} \rightarrow S_{k'_\sigma}$ with $\psi_\sigma^* j_{k'_\sigma} = -j_{k_\sigma}$ for some possibly smaller uniformizing neighbourhood $U_{I_\sigma} \cong \mathbb{R} \times [0, \epsilon)$ with $\epsilon > 0$.

Remark 3.3. Equivalently, we can define a quilted surface \underline{S} by specifying a single surface with strip-like ends \tilde{S} and a finite number of connected, non-intersecting, real analytic submanifolds $\tilde{I}_\sigma \subset \tilde{S}$. (The real analytic condition means that every point $z \in \tilde{I}_\sigma$ has a uniformizing neighbourhood $\tilde{S} \supset \tilde{U} \rightarrow \mathbb{C}$ that maps \tilde{I}_σ to $\mathbb{R} \subset \mathbb{C}$.) We only need to impose a compatibility condition between the seams \tilde{I}_σ and the strip-like ends of \tilde{S} : On every end $\tilde{\epsilon}_e : \mathbb{R}^\pm \times [0, \tilde{\delta}_e] \hookrightarrow \tilde{S}$, the seams are given by straight lines, i.e. $\tilde{\epsilon}_e^{-1}(\tilde{I}_\sigma)$ consists of none, one, or two lines $\mathbb{R}^\pm \times \{t\}$ for pairwise disjoint $t \in [0, \tilde{\delta}_e]$.

The patches S_k of the corresponding quilted surface \underline{S} are then determined by the closures of the connected components of $\tilde{S} \setminus \bigcup_{\sigma \in \mathcal{S}} \tilde{I}_\sigma$. The seams and seam maps are given by the submanifolds \tilde{I}_σ and their embedding into the two (not necessarily different) adjacent connected components. The true boundary components of \underline{S} are exactly the boundary components of \tilde{S} , and the incoming and outgoing quilted ends $\mathcal{E}_-(\underline{S}) \sqcup \mathcal{E}_+(\underline{S})$ are exactly the incoming and outgoing ends of \tilde{S} . Hence orderings of boundary components and ends of \tilde{S} induce the necessary orderings for \underline{S} , with the exception that we need to specify an ordering of the patches.

Eventually, we will see that the relative quilt invariants only depend on the combinatorial structure of a quilted surface, and the specific choice of complex structure, strip-like ends, and seam maps is immaterial. (So it will suffice to define quilted surfaces by pictures as in Figure 5.) The following lemma provides the homotopies for the proof in Section 4.

Lemma 3.4. *Let \underline{S}^0 and \underline{S}^1 be two quilted surfaces of same combinatorial type, i.e. with the same patches $(S_k)_{k=1,\dots,m}$ (as oriented 2-dimensional manifolds with boundary), in- and outgoing marked points $(z_{k,e})$, seams $\sigma \in \mathcal{S}$, and orderings, but possibly different complex structures j_k^i , strip-like ends $\epsilon_{k,e}^i$, and seam maps φ_σ^i for $i = 0, 1$. Then there exists a smooth homotopy $(\underline{S}^\tau)_{\tau \in [0,1]}$ of quilted surfaces, connecting the two. The homotopy is smooth in the sense that j_k^τ , $\epsilon_{k,e}^\tau$, and φ_σ^τ depend smoothly on τ .*

Proof. Since the orientations and combinatorial compatibility with the ends are fixed, we can choose homotopies of diffeomorphisms φ_σ^τ connecting the given seam maps. (This is since $\text{Diff}_+(\mathbb{R}) = \{f \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}) \mid f'(x) > 0 \forall x \in \mathbb{R}, \lim_{x \rightarrow \pm\infty} f(x) = \pm\infty\}$ is convex.) We can moreover choose homotopies of embeddings $\epsilon_{k,e}^\tau|_{\mathbb{R}^\pm \times \{0\}}$ on one boundary component and homotopies $\delta_{k,e}^\tau > 0$ of widths for each marked point. Then the compatibility condition for seams fixes embeddings $\epsilon_{k,e}^\tau|_{\mathbb{R}^\pm \times \{\delta_{k,e}^\tau\}}$ on all other boundary components near marked points, except for those that are true boundary components of \underline{S}^i for which we can choose the homotopy freely. Now, with fixed limits and boundary values, we can find a homotopy of embeddings $\epsilon_{k,e}^\tau$ for each marked point. This fixes the complex structures j_k^τ in neighbourhoods of each marked point. By construction, the seams are automatically real analytic in these neighbourhoods.

Next, recall that we have (anti-holomorphic) embeddings $\psi_\sigma^i : U_\sigma^i \rightarrow S_{k'_\sigma}$ extending the seam maps $\phi_\sigma^i : I_\sigma \rightarrow S_{k'_\sigma}$. We can pick the neighbourhoods to be the same $U_\sigma^i = U_\sigma$ and sufficiently small such that no two neighbourhoods or images thereof intersect each other. Then we choose homotopies of embeddings $\psi_\sigma^\tau : U_\sigma \rightarrow S_{k'_\sigma}$ extending the seam maps ϕ_σ^τ , of standard form $((s, t) \mapsto (s, \delta - t)$ resp. $(s, \delta - t) \mapsto (s, t))$ on the strip-like ends, connecting the given ψ_σ^i , and preserving the empty intersections. Now we can find homotopies of the complex structures $j_{k'_\sigma}^\tau|_{U_\sigma}$ on each of the fixed seam neighbourhoods. This choice induces complex structures $j_{k'_\sigma}^\tau|_{\psi_\sigma^\tau(U_\sigma)} = -(\psi_\sigma^\tau)_* j_{k'_\sigma}^\tau$ on each image of a seam neighbourhood. This construction ensures that the homotopy of seam maps becomes a homotopy of real analytic seams, compatible with the strip-like ends. Finally, we can extend the complex structures to the complement of the strip-like ends and neighbourhoods of seams to find the full homotopy of complex structures j_k^τ on each patch S_k . \square

Elliptic boundary value problems are associated to quilted surfaces with strip-like ends as follows. Suppose that $\underline{E} = (E_k)_{k=1,\dots,m}$ is a collection of complex vector bundles over the patches S_k , and \mathcal{F} is a collection of totally real sub-bundles

$$\mathcal{F} = (F_\sigma)_{\sigma \in \mathcal{S}} \cup (F_b)_{b \in \mathcal{B}}, \quad F_\sigma \subset E_{k'_\sigma}^-|_{I_\sigma} \times \phi_\sigma^*(E_{k'_\sigma}|_{I'_\sigma}), \quad F_b \subset E_{k_b}|_{I_b}.$$

Here we write E^- as short hand for the complex vector bundle with reversed complex structure, $(E, J)^- = (E, -J)$. Let

$$\Omega^0(\underline{S}, \underline{E}; \mathcal{F}) \subset \bigoplus_{k=1}^m \Omega^0(S_k, E_k)$$

denote the subspace of collections of sections $\xi_k \in \Gamma(E_k)$ such that $(\xi_{k_\sigma}, \xi_{k'_\sigma} \circ \varphi_\sigma)$ maps I_σ to F_σ for every seam $\sigma = \{(k_\sigma, I_\sigma), (k'_\sigma, I'_\sigma)\} \in \mathcal{S}$ and ξ_{k_b} maps I_b to F_b for every boundary component $b = (k_b, I_b) \in \mathcal{B}$.

Lemma 3.5. *Suppose that, in a suitable trivialization of the bundles E_k near each end $z_{k,e}$ the subbundles F_σ and F_b are constant and transverse in the sense that for each quilted end $\underline{e} = (k_i, e_i)_{i=1,\dots,n} \in \mathcal{E}(\underline{S})$ we have*

$$(10) \quad F_{b_0} \times F_{\sigma_1} \times \dots \times F_{\sigma_{n-1}} \times F_{b_n} \pitchfork \Delta_{E_{k_1}} \times \Delta_{E_{k_2}} \times \dots \times \Delta_{E_{k_n}}.$$

(Here $\sigma_i \in \mathcal{S}$ are the seams between the ends and $b_0, b_n \in \mathcal{B}$ are the remaining boundary components of the quilted end, resp. σ_n is the additional seam in the case of a cyclic end, in which case we replace $F_{b_n} \times F_{b_0}$ above with F_{σ_n} .) Then the direct sum of Cauchy-Riemann operators

$$D_{\underline{E}, \mathcal{F}} = \bigoplus_{k=1}^m D_{E_k} : \Omega^0(\underline{S}, \underline{E}; \mathcal{F}) \rightarrow \Omega^{0,1}(\underline{S}, \underline{E}) := \bigoplus_{k=1}^m \Omega^{0,1}(S_k, E_k)$$

is Fredholm as a map between the $W^{1,p}$ and L^p Sobolev completions for any $1 < p < \infty$.

Proof. The Fredholm property follows from local estimates for $D_{\underline{E}, \mathcal{F}}$ and its formal adjoint. For sections $\xi_k \in \Gamma(E_k)$ compactly supported in the interior of S_k we have $\|\xi_k\|_{W^{1,p}(S_k)} \leq C(\|D_{E_k} \xi_k\|_{L^p(S_k)} + \|\xi_k\|_{L^p(S_k)})$ as in the standard theory, e.g. [6]. To obtain local estimates near a seam point $z \in I_\sigma$ we use the embedding $\psi_z : S_{k_\sigma} \supset \mathcal{U} \rightarrow S_{k'_\sigma}$ and consider the section $\eta := (\xi_{k_\sigma}, \psi_z^* \xi_{k'_\sigma})$ of $E_{k_\sigma}^-|_{\mathcal{U}} \times \psi_z^* E_{k'_\sigma}$. It satisfies Lagrangian boundary conditions $\eta(\mathcal{U} \cap I_\sigma) \subset F_\sigma$ and, due to the reversal of complex structures in both $E_{k_\sigma}^-$ and by ψ_z^* , the operators $D_{E_{k_\sigma}} \xi_{k_\sigma}$ and $D_{E_{k'_\sigma}} \xi_{k'_\sigma}$ combine to a Cauchy-Riemann operator on η with respect to the complex structure $-j_{k_\sigma}$ on \mathcal{U} . Hence, if ξ_{k_σ} is supported in \mathcal{U} and $\xi_{k'_\sigma}$ is supported in $\psi_z(\mathcal{U})$, then we obtain an estimate

$$\|\xi_{k_\sigma}\|_{W^{1,p}} + \|\xi_{k'_\sigma}\|_{W^{1,p}} \leq C(\|D_{E_{k_\sigma}} \xi_{k_\sigma}\|_{L^p} + \|D_{E_{k'_\sigma}} \xi_{k'_\sigma}\|_{L^p} + \|\xi_{k_\sigma}\|_{L^p} + \|\xi_{k'_\sigma}\|_{L^p}).$$

Finally, given sections $(\xi_k \in \Gamma(E_k))_{k=1, \dots, m}$ supported sufficiently close to the marked points in a quilted end $\underline{e} = (k_i, e_i)_{i=1, \dots, n}$, we can trivialize the bundles $E_{k_i}|_{\text{im } \epsilon_{k_i, e_i}} \cong \mathbb{R}^\pm \times [0, \delta_{k_i, e_i}] \times (V_i, J_i)$ and boundary conditions $F_{\sigma_i} \subset V_i^- \times V_{i+1}$ resp. $F_{b_0} \subset V_1, F_{b_n} \subset V_n$. Then we view the sections as tuple $\underline{\xi} = (\xi_{k_i}|_{\text{im } \epsilon_{k_i, e_i}} : \mathbb{R} \times [0, \delta_{k_i, e_i}] \rightarrow V_i)_{i=1, \dots, n}$ of maps on strips, extended trivially to the complement of $\text{im } \epsilon_{k_i, e_i} \subset \mathbb{R} \times [0, \delta_{k_i, e_i}]$. The (trivialized) Cauchy-Riemann operator on these sections can now be rewritten $D_{\underline{E}, \mathcal{F}}(\xi_k)_{k=1, \dots, m} = (\partial_s + \underline{D})\underline{\xi}$, where $\underline{D} = \bigoplus_{i=1}^n J_i \partial_t$ is a self-adjoint operator on $\bigoplus_{i=1}^n L^2([0, \delta_{k_i, e_i}], V_i)$ whose domain is given by $W^{1,2}$ -maps $\underline{\gamma} = (\gamma_i)_{i=1, \dots, n}$ that satisfy the matching conditions $(\gamma_i(\delta_{k_i, e_i}), \gamma_{i+1}(0)) \in F_{\sigma_i}$ resp. $(\gamma_n(\delta_{k_n, e_n}), \gamma_0(0)) \in F_{b_n} \times F_{b_0}$. The transversality assumption (10) implies that \underline{D} is invertible and hence, as in [10], $\partial_s + \underline{D}$ is a Banach space isomorphism, i.e. for (ξ_k) supported near \underline{e} as above

$$\begin{aligned} \|(\xi_k)\|_{W^{1,2}(\underline{S})} &:= \sum_k \|\xi_k\|_{W^{1,2}(S_k)} = \|\underline{\xi}\|_{W^{1,2}} \\ &\leq C\|(\partial_s + \underline{D})\underline{\xi}\|_{L^2} = C \sum_k \|D_{E_k} \xi_k\|_{L^2(S_k)} =: C\|D_{\underline{E}, \mathcal{F}}(\xi_k)\|_{L^2(\underline{S})}. \end{aligned}$$

This estimate generalizes to $W^{1,p}$ and L^p by the same construction as in [11, Lemma 2.4]. Putting the estimates together we obtain $\|(\xi_k)\|_{W^{1,p}(\underline{S})} \leq C(\|D_{\underline{E}, \mathcal{F}}(\xi_k)\|_{L^p(\underline{S})} + \|K(\xi_k)\|_{L^p(\underline{S})})$ for all $(\xi_k) \in \Omega^0(\underline{S}, \underline{E}; \mathcal{F})$. Here $K : W^{1,p}(\underline{S}) \rightarrow L^p(\underline{S})$ is the restriction operator to some compact subsets of the patches S_k followed by the standard Sobolev inclusion, hence it is a compact operator. This estimate shows that $D_{\underline{E}, \mathcal{F}}$ has finite dimensional kernel and closed image. The analogous estimate for the adjoint operator shows that $D_{\underline{E}, \mathcal{F}}$ has finite dimensional cokernel and hence is Fredholm. \square

In the case that \underline{S} has no strip-like ends, we define a topological index $I(\underline{E}, \mathcal{F})$ as follows. For each patch S_k with boundary we choose a complex trivialization of the bundle $E_k \cong S_k \times \mathbb{C}^{r_k}$. Each bundle $F_b \subset E_{k_b}|_{I_b} \cong I_b \times \mathbb{C}^{r_{k_b}}$ has a Maslov index $I(F_b)$ depending on the trivialization of E_{k_b} . Similarly,

$$F_\sigma \subset E_{k_\sigma}^-|_{I_\sigma} \times \varphi_\sigma^*(E_{k'_\sigma}|_{I'_\sigma}) \cong I_\sigma \times (\mathbb{C}^{r_{k_\sigma}})^- \times \mathbb{C}^{r_{k'_\sigma}}$$

has a Maslov index $I(F_\sigma)$ depending on the trivializations of E_{k_σ} and $E_{k'_\sigma}$. Let $S_0 \subset \underline{S}$ be the union of components without boundary and define

$$I(\underline{E}, \mathcal{F}) := \deg(\underline{E}|_{S_0}) + \sum_{\sigma \in \mathcal{S}} I(F_\sigma) + \sum_{b \in \mathcal{B}} I(F_b).$$

We leave it to the reader to check that the sum is independent of the choice of trivializations. Both the topological and analytic index are invariant under deformation, and by deforming the seam conditions F_σ to those of split form $(\tilde{F}_\sigma \times \tilde{F}'_\sigma)$ with $\tilde{F}_\sigma \subset E_{k_\sigma}^-|_{I_\sigma}$ and $\tilde{F}'_\sigma \subset \phi_\sigma^*(E_{k'_\sigma}|_{I'_\sigma})$ one obtains from (2) an index formula

$$\text{Ind}(D_{\underline{E}, \mathcal{F}}) = \sum_i \text{rank}_{\mathbb{C}}(E_i) \chi(S_i) + I(\underline{E}, \mathcal{F}).$$

We now construct moduli spaces of pseudoholomorphic quilted surfaces. Let

$$\underline{M} = ((M_k, \omega_k))_{k=1, \dots, m}$$

be a collection of symplectic manifolds. A *Lagrangian boundary condition* for $(\underline{S}, \underline{M})$ is a collection

$$\mathcal{L} = (L_\sigma)_{\sigma \in \mathcal{S}} \cup (L_b \subset M_{k_b})_{b \in \mathcal{B}}, \quad L_\sigma \subset M_{k_\sigma}^- \times M_{k'_\sigma}, \quad L_b \subset M_{k_b}$$

of Lagrangian correspondences and Lagrangian submanifolds associated to the seams and boundary components of the quilted surface. We will indicate the domains M_k , the seam conditions L_σ , and the true boundary conditions L_b by marking the surfaces, seams and boundaries of the quilted surfaces as in figure 6.

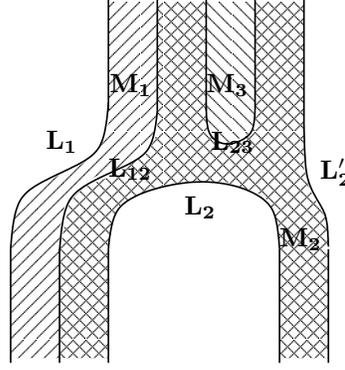

Figure 6. Lagrangian boundary conditions for a quilt

We say that the tuples \underline{M} and \mathcal{L} are *graded* if each M_k is equipped with an N -fold Maslov covering for a fixed $N \in \mathbb{N}$ and each Lagrangian $L_\sigma \subset M_{k_\sigma}^- \times M_{k'_\sigma}$ and $L_b \subset M_{k_b}$ is graded with respect to the respective Maslov covering. Moreover, we assume that the gradings are compatible with orientations in the sense of (G1-2).

We say that \mathcal{L} is *relatively spin* if all Lagrangians in the tuple are relatively spin with respect to one fixed set of background classes $b_k \in H^2(M_k, \mathbb{Z}_2)$, see [20].

Definition 3.6. We say that the tuple of Lagrangian boundary and seam conditions \mathcal{L} for \underline{S} is *monotone* if the sequences $\underline{L}_\underline{e}$ in (11) resp. (12) below for each end $\underline{e} \in \mathcal{E}(\underline{S})$ are monotone for Floer theory (in the sense of [19]) and the following holds: Let $\underline{S} \# \underline{S}^-$ denote the quilted surface obtained by gluing a copy \underline{S}^- of \underline{S} with reversed complex structure (and hence reversed ends) to \underline{S} at all corresponding ends. This quilted surface has components $(S_k \# S_k^-)_{k=1, \dots, m}$, compact seams $\phi_\sigma : I_\sigma \xrightarrow{\sim} I'_\sigma \cong S^1$ for $\sigma \in \tilde{\mathcal{S}}$ (one for each noncompact and two for each compact seam of \underline{S}), compact boundary components $I_b \cong S^1$ for $b \in \tilde{\mathcal{B}}$ (one for each noncompact and two for each compact boundary component of \underline{S}), but no strip-like ends. Then for each tuple of maps $\underline{u} : \underline{S} \# \underline{S}^- \rightarrow \underline{M}$ (that is $u_k : S_k^- \# S_k \rightarrow M_k$) that takes values in \mathcal{L} over the seams and boundary components (that is $(u_{k_\sigma} \times u_{k'_\sigma} \circ \phi_\sigma)(I_\sigma) \subset L_\sigma$ and $u_k(I_b) \subset L_b$) we have the action-index relation

$$2 \sum_{k=1}^m \int u_k^* \omega_k = \tau \cdot I(\underline{E}_u, \mathcal{F}_u)$$

for $\underline{E}_u = (u_k^* T M_k)_{k=1, \dots, m}$ and $\mathcal{F}_u = ((u_{k_\sigma} \times u_{k'_\sigma} \circ \phi_\sigma)^* T L_\sigma)_{\sigma \in \tilde{\mathcal{S}}} \cup (u_{k_b}^* T L_b)_{b \in \tilde{\mathcal{B}}}$.

Remark 3.7. Note the following analogue of the monotonicity Lemma in [19]: If each M_k is monotone in the sense of (M1) and each L_σ and L_b is monotone in the sense of (L1), all with the same constant $\tau \geq 0$, and each $\pi_1(L_\sigma) \rightarrow \pi_1(M_{k_\sigma}^- \times M_{k'_\sigma})$ and $\pi_1(L_b) \rightarrow \pi_1(M_{k_b})$ has torsion image, then \mathcal{L} is monotone. This is because any tuple \underline{u} in Definition 3.6 is homotopic to the union of a disc $(D, \partial D) \rightarrow (M_{k_\sigma}^- \times M_{k'_\sigma}, L_\sigma)$ at each seam, a disc $(D, \partial D) \rightarrow (M_{k_b}, L_b)$ at each true boundary component of the quilt, and a closed curve $\Sigma_k \rightarrow M_k$ for each patch.

To each quilted end $\underline{e}_\pm = (k_i, e_i)_{i=1, \dots, n} \in \mathcal{E}_\pm(\underline{\mathcal{S}})$ we associate the sequence of Lagrangian correspondences of length $n = n_{\underline{e}}$ that label the seams and boundary components which run into the end. For an incoming quilted end \underline{e}_- the seams between the ends of the patches are $\phi_{\sigma_i} : I_{\sigma_i} = I_{k_i, e_{i-1}} \xrightarrow{\sim} I'_{\sigma_i} = I_{k_{i+1}, e_{i+1}}$ for $i = 1, \dots, n-1$, whereas for an outgoing quilted end \underline{e}_+ the seams are $\phi_{\sigma_i} : I_{\sigma_i} = I_{k_i, e_i} \xrightarrow{\sim} I'_{\sigma_i} = I_{k_{i+1}, e_{i+1}-1}$. In both cases $\epsilon_{k_{i+1}, e_{i+1}}^{-1} \circ \phi_{\sigma_i} \circ \epsilon_{k_i, e_i}$ is the map $(s, \delta_{k_i, e_i}) \mapsto (s, 0)$ for $s \in \mathbb{R}^\pm$. The end could be cyclic, i.e. with an additional seam $\phi_{\sigma_n} : I_{k_n, e_{n-1}} \xrightarrow{\sim} I_{k_1, e_1}$ resp. $\phi_{\sigma_n} : I_{k_n, e_n} \xrightarrow{\sim} I_{k_1, e_1-1}$. In that case the generalized Lagrangian correspondence associated to the end \underline{e} is the cyclic correspondence

$$(11) \quad \underline{L}_{\underline{e}} := (L_{\sigma_1}, \dots, L_{\sigma_{n-1}}, L_{\sigma_n}) = (\longrightarrow M_{k_1} \xrightarrow{L_{\sigma_1}} M_{k_2} \dots \xrightarrow{L_{\sigma_{n-1}}} M_{k_n} \xrightarrow{L_{\sigma_n}}).$$

If the end is noncyclic then the boundary components $I_{k_1, e_1} = I_{b_0}$ and $I_{k_n, e_{n-1}} = I_{b_n}$ in the incoming case, resp. $I_{k_1, e_1-1} = I_{b_0}$ and $I_{k_n, e_n} = I_{b_n}$ in the outgoing case, are true boundary components of the quilted surface $\underline{\mathcal{S}}$. In that case the generalized Lagrangian correspondence associated to the end \underline{e} is the correspondence

$$(12) \quad \underline{L}_{\underline{e}} := (L_{b_0}, L_{\sigma_1}, \dots, L_{\sigma_{n-1}}, L_{b_n}) = (\{pt\} \xrightarrow{L_{b_0}} M_{k_1} \xrightarrow{L_{\sigma_1}} M_{k_2} \dots \xrightarrow{L_{\sigma_{n-1}}} M_{k_n} \xrightarrow{L_{b_n}} \{pt\}).$$

Equivalently, for a noncyclic end, the correspondence L_{σ_n} in (11) is replaced by the split type Lagrangian correspondence $L_{b_n} \times L_{b_0} \subset M_{k_n}^- \times M_{k_1}$.

Associated to each quilted end $\underline{e} \in \mathcal{E}(\underline{\mathcal{S}})$ we moreover have the widths $\delta_{\underline{e}} = (\delta_{k_i, e_i})_{i=1, \dots, n_{\underline{e}}}$ of the strip-like ends that constitute \underline{e} . Given $\delta_{\underline{e}}$ and assuming monotonicity as above, we can now as in [19] fix regular Hamiltonian perturbations $\underline{H}_{\underline{e}} = (H_{k_i, e_i})_{i=1, \dots, n_{\underline{e}}}$ and almost complex structures $\underline{J}_{\underline{e}} = (J_{k_i, e_i})_{i=1, \dots, n_{\underline{e}}}$ such that the quilted Floer homology $HF(\underline{L}_{\underline{e}})$ is well defined. In particular, the generalized intersection points of the correspondence are a finite set for each end $e \in \mathcal{E}(\underline{\mathcal{S}})$,

$$\mathcal{I}(\underline{L}_{\underline{e}}) = L_{b_0} \times_{\phi_1} L_{\sigma_1} \times_{\phi_2} \dots \times_{\phi_n} L_{b_n} \subset \prod_{i=1}^n M_{k_i}$$

resp.

$$\mathcal{I}(\underline{L}_{\underline{e}}) = \times_{\phi_1} (L_{\sigma_1} \times_{\phi_2} \dots \times_{\phi_n} L_{\sigma_n}) \subset \prod_{i=1}^n M_{k_i}.$$

Here ϕ_i denotes the time δ_{k_i, e_i} flow of the Hamiltonian H_{k_i, e_i} on M_{k_i} . Next, let $\text{Ham}(\underline{\mathcal{S}}, (\underline{H}_{\underline{e}})_{\underline{e} \in \mathcal{E}})$ denote the set of tuples

$$\underline{K} = (K_k \in \Omega^1(S_k, C^\infty(M_k)))_{k=1, \dots, m}$$

such that $K_k|_{\partial S_k} = 0$ and on each end $\epsilon_{k, e}^* K_k = H_{k, e} dt$. We denote the corresponding Hamiltonian vector field valued one-forms by $\underline{Y} \in \Omega^1(\underline{\mathcal{S}}, \text{Vect}(\underline{M}))$. These satisfy $\epsilon_{k, e}^* Y_k = X_{H_{k, e}} dt$ on each strip-like end. Next, let $\mathcal{J}(\underline{\mathcal{S}}, (\underline{J}_{\underline{e}})_{\underline{e} \in \mathcal{E}})$ denote the set of collections

$$\underline{J} = (J_k \in \text{Map}(S_k, \mathcal{J}(M_k, \omega_k)))_{k=1, \dots, m}$$

agreeing with the chosen almost complex structures on the ends. Now we denote by $\underline{\mathcal{I}}_-(\underline{\mathcal{S}}, \underline{\mathcal{L}})$ resp. $\underline{\mathcal{I}}_+(\underline{\mathcal{S}}, \underline{\mathcal{L}})$ the set of tuples $X^\pm = (\underline{x}_{\underline{e}}^\pm)_{\underline{e} \in \mathcal{E}_\pm(\underline{\mathcal{S}})}$ consisting of one intersection tuple $\underline{x}_{\underline{e}}^\pm = (x_{k_i, e_i}^\pm)_{i=1, \dots, n_{\underline{e}}} \in \mathcal{I}(\underline{L}_{\underline{e}})$ for each incoming resp. outgoing end \underline{e} . For each pair $(X^-, X^+) \in \underline{\mathcal{I}}_-(\underline{\mathcal{S}}, \underline{\mathcal{L}}) \times \underline{\mathcal{I}}_+(\underline{\mathcal{S}}, \underline{\mathcal{L}})$ we introduce a moduli space of *pseudoholomorphic quilts*:

$$\mathcal{M}_{\underline{\mathcal{S}}}(X^-, X^+) := \{\underline{u} = (u_k : S_k \rightarrow M_k)_{k=1, \dots, m} \mid (a) - (d)\}$$

is the space of collections of $(\underline{J}, \underline{K})$ -holomorphic maps with Lagrangian boundary and seam conditions, finite energy, and fixed limits, that is

- a) $\bar{\partial}_{J_k, K_k} u_k := J_k(u_k) \circ (du_k - Y_k(u_k)) - (du_k - Y_k(u_k)) \circ j_k = 0$ for $k = 1, \dots, m$,
- b) $(u_{k_\sigma}, u_{k'_\sigma} \circ \varphi_\sigma)(I_\sigma) \subset L_\sigma$ for all $\sigma \in \mathcal{S}$ and $u_k(I_b) \subset L_b$ for all $b \in \mathcal{B}$.
- c) $E_{\underline{K}}(\underline{u}) = \sum_{k=1}^m E_{K_k}(u_k) < \infty$,

d) $\lim_{s \rightarrow \pm\infty} u_{k_i}(\epsilon_{k_i, e_i}(s, t)) = x_{k_i, e_i}^\pm(t)$ for all $\underline{e} = (k_i, e_i)_{i=1, \dots, n_{\underline{e}}} \in \mathcal{E}_\pm(\underline{S})$.

Remark 3.8. 1) To show that (a)–(d) defines a Fredholm problem we proceed as usual (see e.g. [6]): Construct a Banach manifold \mathcal{B} of tuples of maps satisfying (b)–(d) and show that the tuples satisfying (a) are the zeros of a Fredholm section $\bar{\partial}_{J, \underline{K}}$ of the bundle $\mathcal{E} \rightarrow \mathcal{B}$ of tuples of $(0, 1)$ -forms. As in Remark 2.2 we also define the linearized operator $D_{\underline{u}} = d\sigma_{\underline{u}}(0)$ at a not necessarily holomorphic $\underline{u} \in \mathcal{B}$ from a map $\sigma_{\underline{u}} : T_{\underline{u}}\mathcal{B} \rightarrow \mathcal{E}_{\underline{u}}$ given by $\sigma_{\underline{u}}(\underline{\xi}) = \Phi_{\underline{u}}(\underline{\xi})^{-1}(\bar{\partial}_{J, \underline{K}}(\exp_{\underline{u}}(\underline{\xi})))$ and suitable quadratic corrections. To be more precise, the tangent space $T_{\underline{u}}\mathcal{B}$ is a Sobolev completion of the space of tuples of sections $\underline{\xi}$ of the complex bundles $\underline{E}_{\underline{u}} = (u_k^* T M_k)_{k=1, \dots, m}$ satisfying boundary and seam conditions in the totally real subbundles $\mathcal{F}_{\underline{u}} = ((u_{k_\sigma} \times u_{k'_\sigma} \circ \phi_\sigma)^* T L_\sigma)_{\sigma \in \mathcal{S}} \cup (u_{k_b}^* T L_b)_{b \in \mathcal{B}}$. The component of $\sigma_{\underline{u}}(\underline{\xi})$ on the patch S_k is the $(0, 1)$ -form $\Phi_{u_k}(\underline{\xi})^{-1}(\bar{\partial}_{J_k, K_k}(\exp_{u_k}^0(\xi_k + Q_k(\underline{\xi})))$, where $Q_k(\underline{\xi}) \in u_k^* T M_k$ is a quadratic correction, \exp^0 is the standard exponential map using a fixed metric on M_k , and $\Phi_{u_k}(\underline{\xi})$ is parallel transport with the usual complex linear connection on $T^* M_k$ along the paths $s \mapsto \exp_u^0(s\xi_k + Q_k(s\underline{\xi}))$. The quadratic correction $Q_k(\underline{\xi})$ vanishes on the complement of uniformizing neighbourhoods of ∂S_k . Near a true boundary component $I_b \subset \partial S_k$ the correction actually only depends on ξ_k and is given exactly as in Remark 2.2 by interpolating between the fixed metric on M_k and a metric in which $L_b \subset M_k$ is totally geodesic. Near a seam $I_\sigma \subset \partial S_k$ that connects the patches S_k and $S_{k'}$ we use the extended seam map $\psi_\sigma : \mathcal{U}_{I_\sigma} \rightarrow S_{k'}$ of Remark 3.2 to pair $(u_k, u_{k'})$ and $(\xi_k, \xi_{k'})$ to $u_\sigma : \mathcal{U}_{I_\sigma} \rightarrow M_k^- \times M_{k'}$ and $\xi_\sigma \in u_\sigma^* T(M_k^- \times M_{k'})$. Now the quadratic corrections $(Q_k(\underline{\xi}), Q_{k'}(\underline{\xi}))$, viewed as one section $Q_\sigma(\xi_k, \xi_{k'}) \in u_\sigma^* T(M_k^- \times M_{k'})$ are given by interpolating the fixed product of metrics on M_k and $M_{k'}$ to a metric on $M_k^- \times M_{k'}$ in which L_σ is totally geodesic.

Thus the S_k -component of $\sigma_{\underline{u}}(\underline{\xi})$ in a neighbourhood of the seam I_σ actually also depends on the section $\xi_{k'}$ via the quadratic correction. However, since $Q(0) = 0$ and $dQ(0) = 0$ as in Remark 2.2, the linearized operator constructed in this way is independent of the choice of quadratic correction and takes the same form as in [6] on each patch. So it takes the form $D_{\underline{u}} = D_{\underline{E}_{\underline{u}}, \mathcal{F}_{\underline{u}}}$ of a direct sum of real Cauchy-Riemann operators as discussed in the linear theory above.

2) If \mathcal{L} is monotone, then elements $\underline{u} \in \mathcal{M}_{\underline{S}}(X^-, X^+)$ (and more generally tuples of maps as in (1) above) satisfy an energy-index relation

$$(13) \quad 2E_{\underline{K}}(\underline{u}) = \tau \cdot \text{Ind}(D_{\underline{u}}) + c(X^-, X^+)$$

The identity follows as in Remark 2.2 by gluing a fixed element $\underline{v}_0 \in \mathcal{M}_{\underline{S}}(X^-, X^+)$ to \underline{u} to obtain a quilt map $\underline{w} = \underline{u} \# \underline{v}_0$ defined on $\underline{S} \# \underline{S}'$, which satisfies the monotonicity relation by Definition 3.6.

3) If all Lagrangians in \mathcal{L} are oriented, then for any tuple \underline{u} as in (1) the index $\text{Ind}(D_{\underline{u}})$ is determined mod 2 by \underline{S} and the limit conditions X^-, X^+ . This also follows as in Remark 2.2 from the index identity $\text{Ind}(D_{\underline{u}}) + \text{Ind}(D_{\underline{v}_0}) = \text{Ind}(D_{\underline{w}}) = I(\underline{E}_{\underline{w}}, \mathcal{F}_{\underline{w}}) + \sum_{k=1}^m \frac{\dim M_k}{2} \chi(S_k \# S_k^-)$, where the topological index $I(\underline{E}_{\underline{w}}, \mathcal{F}_{\underline{w}})$ is even since each of the totally real subbundles in $\mathcal{F}_{\underline{w}}$ has an orientation induced from the orientations of the seam and boundary conditions L_σ and L_b .

Theorem 3.9. *Suppose that each M_k satisfies (M1-2), each Lagrangian in \mathcal{L} satisfies (L1-2), and \mathcal{L} is monotone in the sense of Definition 3.6. Moreover, for any end $\underline{e} \in \mathcal{E}(\underline{S})$ fix regular perturbation data $(\underline{H}_{\underline{e}}, \underline{J}_{\underline{e}})$. Then for any $\underline{K} \in \text{Ham}(\underline{S}, (\underline{H}_{\underline{e}})_{\underline{e} \in \mathcal{E}})$ there exists a dense comeagre subset $\mathcal{J}(\underline{S}, (\underline{J}_{\underline{e}})_{\underline{e} \in \mathcal{E}}, \underline{K})^{\text{reg}} \subset \mathcal{J}(\underline{S}, (\underline{J}_{\underline{e}})_{\underline{e} \in \mathcal{E}})$ such that for all $X^\pm \in \underline{\mathcal{I}}_\pm(\underline{S}, \mathcal{L})$*

- a) $\mathcal{M}_{\underline{S}}(X^-, X^+)$ is a smooth manifold whose dimension near a solution \underline{u} is given by the formal dimension $\text{Ind}(D_{\underline{u}})$;
- b) The zero dimensional component $\mathcal{M}_{\underline{S}}(X^-, X^+)_0$ is finite;

- c) The one-dimensional component $\mathcal{M}_{\underline{S}}(X^-, X^+)_1$ has a compactification as a one-manifold with boundary

$$\begin{aligned} \overline{\mathcal{M}_{\underline{S}}(X^-, X^+)_1} \cong & \bigcup_{\underline{e} \in \mathcal{E}_-, \underline{y} \in \mathcal{I}(\underline{L}_{\underline{e}})} \mathcal{M}(\underline{x}_{\underline{e}}^-, \underline{y})_0 \times \mathcal{M}_{\underline{S}}(X^-|_{\underline{x}_{\underline{e}}^- \rightarrow \underline{y}}, X^+)_0 \\ & \bigcup_{\underline{e} \in \mathcal{E}_+, \underline{y} \in \mathcal{I}(\underline{L}_{\underline{e}})} \mathcal{M}_{\underline{S}}(X^-, X^+|_{\underline{x}_{\underline{e}}^+ \rightarrow \underline{y}})_0 \times \mathcal{M}(\underline{y}, \underline{x}_{\underline{e}}^+)_0. \end{aligned}$$

Here the multi-tuple $X|_{\underline{x}_{\underline{e}} \rightarrow \underline{y}}$ is X with the tuple $\underline{x}_{\underline{e}}$ replaced by \underline{y} , and $\mathcal{M}(\underline{x}^-, \underline{x}^+)$ for $\underline{x}^{\pm} \in \mathcal{I}(\underline{L}_{\underline{e}})$ are the moduli spaces of quilted Floer trajectories defined in [19] with the perturbation data $\underline{\delta}_{\underline{e}}, \underline{H}_{\underline{e}}, \underline{J}_{\underline{e}}$.

- d) If \mathcal{L} is relatively spin, then there exists a coherent set of orientations on the zero and one-dimensional moduli spaces so that the inclusion of the boundary in (c) has the signs $(-1)^{\sum_{\underline{I} < \underline{e}} |\underline{x}_{\underline{I}}^-|}$ (for incoming trajectories) and $-(-1)^{\sum_{\underline{I} < \underline{e}} |\underline{x}_{\underline{I}}^+|}$ (for outgoing trajectories.)

Proof. The proof requires no new or nonstandard techniques except for the observation that a pseudoholomorphic quilt with seam condition in a Lagrangian correspondence is locally equivalent to a pseudoholomorphic curve with boundary condition in a Lagrangian. Formally, consider any point $z \in I_{\sigma}$ on a seam $\sigma \in \mathcal{S}$. Since the seam is assumed to be real analytic we have an embedding $\psi : \mathcal{U} \rightarrow S_{k'_{\sigma}}$ of a neighbourhood $\mathcal{U} \subset S_{k_{\sigma}}$ of z that restricts to the seam map $\psi|_{\mathcal{U} \cap \partial S_k} = \varphi_{\sigma}|_{\mathcal{U} \cap I_{\sigma}} : \mathcal{U} \cap I_{\sigma} \rightarrow I'_{\sigma}$. Given any tuple of maps $\underline{u} = (u_k : S_k \rightarrow M_k)_{k=1, \dots, m}$ consider the map $w := (u_{k_{\sigma}}|_{\mathcal{U}}, u_{k'_{\sigma}} \circ \psi) : \mathcal{U} \rightarrow M_{k_{\sigma}}^- \times M_{k'_{\sigma}}$. The perturbed holomorphic equation in (a) for k_{σ} on \mathcal{U} and for k'_{σ} on $\psi(\mathcal{U})$ is equivalent to the perturbed holomorphic equation $J_{\sigma}(w) \circ (dw - Y_{\sigma}(w)) = (dw - Y_{\sigma}(w)) \circ (-j_{k_{\sigma}})$ on \mathcal{U} . Here the almost complex structure $J_{\sigma} := (-J_{k_{\sigma}}) \oplus J_{k'_{\sigma}} \circ \psi^{-1} \in \mathcal{C}^{\infty}(\mathcal{U}, \mathcal{J}(M_{k_{\sigma}} \times M_{k'_{\sigma}}, \omega_{\sigma}))$ is compatible with the symplectic form $\omega_{\sigma} := (-\omega_{k_{\sigma}}) \oplus \omega_{k'_{\sigma}}$, and the perturbation $Y_{\sigma} := Y_{k_{\sigma}}|_{\mathcal{U}} \oplus \psi^* Y_{k'_{\sigma}} \in \Omega^1(\mathcal{U}, \text{Vect}(M_{k_{\sigma}} \times M_{k'_{\sigma}}))$, which corresponds to the Hamiltonian-valued one-form $K_{\sigma} := K_{k_{\sigma}}|_{\mathcal{U}} + \psi^* K_{k'_{\sigma}} \in \Omega^1(\mathcal{U}, \mathcal{C}^{\infty}(M_{k_{\sigma}} \times M_{k'_{\sigma}}))$. The seam condition in (b) for σ on $\mathcal{U} \cap I_{\sigma}$ is equivalent to $w(\mathcal{U} \cap I_{\sigma}) \subset L_{\sigma}$, and the contribution to the energy in (c) on \mathcal{U} and $\psi(\mathcal{U})$ is

$$\int_{\mathcal{U}} (u_{k_{\sigma}}^* \omega_{k_{\sigma}} + d(K_{k_{\sigma}} \circ u_{k_{\sigma}})) + \int_{\psi(\mathcal{U})} (u_{k'_{\sigma}}^* \omega_{k'_{\sigma}} + d(K_{k'_{\sigma}} \circ u_{k'_{\sigma}})) = \int_{\mathcal{U}} (w^* \omega_{\sigma} + d(K_{\sigma} \circ w)).$$

On the quilted ends we have exponential decay by the same arguments as in [19]: The quilted end can be seen as one simple strip-like end with values in a product of manifolds and a deformed almost complex structure (where the deformation only stems from the different widths of strips). Here we require just the finiteness of energy. For the compactness of moduli spaces we will need the energy actually bounded, which follows from the energy-index relation (13) when fixing the index.

The proof of compactness follows the strategy in Lemma 3.5. We have local energy bounds in the interior of patches, in a neighbourhood of any boundary point, and in the above ‘‘folded neighbourhoods’’ around seams. The standard estimates (e.g. as in [6]) for holomorphic curves in these neighbourhoods combine to prove compactness if we can exclude bubbling, i.e. prove uniform gradient bounds. In the case of noncompact symplectic manifolds we moreover need to establish a \mathcal{C}^0 -bound on the curves. The latter follows from uniform gradient bounds together with the compactness of the Lagrangian boundary and seam conditions, since we do not allow patches without boundary. Bubbling effects can be analyzed locally, either in the interior of a single patch or in a seam neighbourhood as above. Local rescaling near points in a seam neighbourhood where the gradient blows up leads to spheres in $M_{k_{\sigma}}^- \times M_{k'_{\sigma}}$, or to discs with boundary on L_{σ} .⁷ These are

⁷In the case of noncompact symplectic manifolds, this is the one point that requires additional attention. If the manifold has convex ends, then the maximum principle guarantees that all relevant holomorphic curves are contained in a fixed compact set, hence we obtain convergence to a sphere or disk. More generally, one could argue with monotonicity and an energy quantization argument as in [16], which only requires uniform bounds on the second derivatives of the almost complex structures.

ruled out, for the zero and one-dimensional moduli spaces, by the energy-index relation and the assumptions (M1) and (L1-2) which ensure that two holomorphic quilts with the same ends but different energy differ in index by at least 2, see Remark 3.8. So the limit solution after removal of singularity at the bubbling points would have negative index. However, assuming transversality, this moduli space is empty.

To achieve transversality we can work with almost complex structures on each patch of the quilt. They are fixed (and only t -dependent) on the strip-like ends, but can vary freely on the rest of each patch. By unique continuation on the ends, each element in the cokernel must be nonzero somewhere in the complement of the strip-like ends. This can be excluded by an appropriate variation of the almost complex structure on this complement, given by the Sard-Smale theorem from a transverse universal moduli space.

The gluing construction, which shows the reverse inclusion in (c), is local near each quilted end in the sense that it uses only the non-degeneracy of operator on the neck and the regularity of the linearized operators for the Floer trajectories, which hold by the choice of the perturbation data.

Finally, orientations are defined, and coherence is proven in [20]. \square

Associated to the data $(\underline{S}, \underline{M}, \mathcal{L})$ as in Theorem 3.9 we construct a relative invariant $\Phi_{\underline{S}}$ as follows. Define

$$C\Phi_{\underline{S}}: \bigotimes_{\underline{e} \in \mathcal{E}_-(\underline{S})} CF(\underline{L}_{\underline{e}}) \rightarrow \bigotimes_{\underline{e} \in \mathcal{E}_+(\underline{S})} CF(\underline{L}_{\underline{e}})$$

by

$$C\Phi_{\underline{S}}\left(\bigotimes_{\underline{e} \in \mathcal{E}_-} \langle \underline{x}_{\underline{e}}^- \rangle\right) := \sum_{X^+ \in \underline{\mathcal{L}}_+(\underline{S}, \mathcal{L})} \left(\sum_{\underline{u} \in \mathcal{M}_{\underline{S}}(X^-, X^+)_0} \epsilon(u) \right) \bigotimes_{\underline{e} \in \mathcal{E}_+} \langle \underline{x}_{\underline{e}}^+ \rangle,$$

where

$$\epsilon: \mathcal{M}_{\underline{S}}(X^-, X^+)_0 \rightarrow \{-1, +1\}$$

is defined by comparing the orientation given by Theorem 3.9 (d) to the canonical orientation of a point. By items (c),(d) of Theorem 3.9, the maps $C\Phi_{\underline{S}}$ are chain maps and so descend to a map of Floer cohomologies

$$(14) \quad \Phi_{\underline{S}}: \bigotimes_{\underline{e} \in \mathcal{E}_-(\underline{S})} HF(\underline{L}_{\underline{e}}) \rightarrow \bigotimes_{\underline{e} \in \mathcal{E}_+(\underline{S})} HF(\underline{L}_{\underline{e}}).$$

Here we assume in addition that all Lagrangians in \mathcal{L} satisfy (L3) and hence the Floer cohomologies are well defined. In Section 4 below we will see that the relative invariants $\Phi_{\underline{S}}$ are indeed invariants of the symplectic data $(\underline{M}, \mathcal{L})$ and the combinatorial data of the quilted surface \underline{S} , i.e. they are independent of the choices of perturbation data $(\underline{K}, \underline{J})$, complex structures $\underline{j} = (j_k)_{k=1, \dots, m}$, strip-like ends on each S_k , and seam maps $\underline{\phi} = (\phi_{\sigma})_{\sigma \in \mathcal{S}}$.

Remark 3.10. The effect of the relative invariant $\Phi_{\underline{S}}$ on the grading is by a shift in degree of

$$(15) \quad |\Phi_{\underline{S}}| = \sum_{k=1}^m \frac{1}{2} \dim M_k (\#\mathcal{E}_+(S_k) - \chi(\overline{S}_k)) \pmod{N}.$$

To check this we consider an isolated solution $\underline{u} \in \mathcal{M}_{\underline{S}}(X^-, X^+)_0$. At each end $\underline{e} \in \mathcal{E}(\underline{S})$ we can deform the linearized seam conditions

$$(16) \quad (T_{(x_{k_1, e_1}, x_{k_2, e_2})} L_{\sigma_1}, T_{(x_{k_2, e_2}, x_{k_3, e_3})} L_{\sigma_2}, \dots, T_{(x_{k_n, e_n}, x_{k_1, e_1})} L_{\sigma_n})$$

(and similar in the noncyclic case) to split type,

$$(17) \quad (\Lambda'_{\underline{e}, 1} \times \Lambda_{\underline{e}, 2}, \Lambda'_{\underline{e}, 2} \times \Lambda_{\underline{e}, 3}, \dots, \Lambda'_{\underline{e}, n} \times \Lambda_{\underline{e}, 1})$$

for Lagrangian subspaces $\Lambda_{\underline{e}, j}, \Lambda'_{\underline{e}, j} \subset T_{x_{k_j, e_j}} M_{k_j}$, without changing the index. This is possible since the space of Lagrangian subspaces transverse to a given one is always connected. To be more precise, we can first homotope the Hamiltonian perturbations H_{k_j, e_j} on the end to zero while moving the

Lagrangians by a Hamiltonian isotopy ($\phi^{H_{k_j, e_j}}$ acts on the second factor in $T_{(x_{k_{j-1}, e_{j-1}}, x_{k_j, e_j})} L_{\sigma_{j-1}}$). This deforms the linearized operator $D_{\underline{u}}$ through Fredholm operators to another direct sum of Cauchy-Riemann operators. Next, homotoping the boundary conditions in (16) does not affect the Fredholm property (and hence preserves the index) as long as the product of correspondences remains transverse to the diagonal $(\Delta_{M_{k_1}} \times \Delta_{M_{k_2}} \times \dots \times \Delta_{M_{k_n}})^T$, where $(\cdot)^T$ shifts the first M_{k_1} factor to the end to obtain a Lagrangian submanifold of $M_{k_1}^- \times M_{k_2}^- \times \dots \times M_{k_n}^- \times M_{k_1}$. Transversality of the split boundary conditions (17) then means that each pair $\Lambda_{\underline{e}, j} \pitchfork \Lambda'_{\underline{e}, j}$ is transverse.

Now [19, Lemma 3.1.5] expresses the degree of each end as sum $|\underline{x}_{\underline{e}}| = \sum_{j=1}^{n_{\underline{e}}} d(\tilde{\Lambda}_{\underline{e}, j}, \tilde{\Lambda}'_{\underline{e}, j})$, and summing this over all incoming resp. outgoing ends \underline{e} of $\underline{\mathcal{S}}$ is the same as summing $d(\Lambda_{k, e}^0, \Lambda_{k, e}^1)$ over all incoming resp. outgoing ends e of all patches S_k . Here the transverse pair $\Lambda_{k, e}^0 \pitchfork \Lambda_{k, e}^1 \subset T_{x_{k, e}} M_k$ of boundary conditions at $e \in \mathcal{E}(S_k)$ corresponds to a unique pair $\Lambda_{\underline{e}, j} \pitchfork \Lambda'_{\underline{e}, j} \subset T_{x_{k_j, e_j}} M_k$ for some quilted end $\underline{e} \in \mathcal{E}(\underline{\mathcal{S}})$ and $j = 1, \dots, n_{\underline{e}}$ with $k_j = k$.

Next, we deform the linearized boundary conditions with fixed ends to split type over each seam. Again, this does not affect the index since it is a homotopy of Fredholm operators. We thus obtain a splitting of the index $0 = \sum_{k=1}^m \text{Ind}(D_{E_k, \mathcal{F}_k})$ into the indices of Cauchy-Riemann operators on $E_k = u_k^* T M_k$ with boundary conditions in totally real subbundles $\mathcal{F}_k \subset E_k|_{\partial S_k}$. From Remark 2.4 we have a mod N degree index identity for each surface,

$$\frac{1}{2} \chi(\overline{S}_k) \dim M_k = \text{Ind}(D_{E_k, \mathcal{F}_k}) + \sum_{e \in \mathcal{E}_+(S_k)} \left(\frac{1}{2} \dim M_k - d(\tilde{\Lambda}_e^0, \tilde{\Lambda}_e^1) \right) + \sum_{e \in \mathcal{E}_-(S_k)} d(\tilde{\Lambda}_e^0, \tilde{\Lambda}_e^1).$$

So, summing over all surfaces S_k we obtain as claimed

$$\sum_{k=1}^m \frac{1}{2} \dim M_k (\chi(\overline{S}_k) - \#\mathcal{E}_+(S_k)) = - \sum_{\underline{e} \in \mathcal{E}_+(\underline{\mathcal{S}})} |\underline{x}_{\underline{e}}^+| + \sum_{\underline{e} \in \mathcal{E}_-(\underline{\mathcal{S}})} |\underline{x}_{\underline{e}}^-| \quad \text{mod } N.$$

Remark 3.11. When working with \mathbb{Z} coefficients, then changing the ordering of the patches (and hence their boundary components) in $\underline{\mathcal{S}}$ changes the relative invariant $\Phi_{\underline{\mathcal{S}}}$ by a universal sign. These signs are only affected by the ordering of patches S_k whose deficiency $\#\mathcal{E}_+(S_k) - b(S_k)$ is odd. Here $b(S_k)$ denotes the number of boundary components of \overline{S}_k . We will not mention ordering for patches of even deficiency, e.g. for patches with one boundary component and one outgoing end.

Remark 3.12. As in Remark 2.11, one can also allow those component surfaces labeled by compact symplectic manifolds to have incoming and outgoing cylindrical ends. In this case, the relative invariants (14) have additional factors of cylindrical Floer homologies $HF(\text{Id}_{M_k})$ on either side.

The gluing theorem 2.7 generalize to the quilted case as follows. Unfortunately, the explicit gluing sign is too complicated to write down even in the special case of a disjoint union of quilted surfaces.

Theorem 3.13 (Quilted Gluing Theorem). *Suppose that $\underline{e}_{\pm} = (k_i^{\pm}, e_i^{\pm})_{i=1, \dots, N} \in \mathcal{E}_{\pm}(\underline{\mathcal{S}})$ are ends with $n_{\underline{e}_-} = n_{\underline{e}_+} = N$ and such that the data $M_{k_i^-, e_i^-} = M_{k_i^+, e_i^+}$ and $\underline{L}_{\underline{e}_-} = \underline{L}_{\underline{e}_+}$ coincide. Then we have*

$$(18) \quad \Phi_{\#\underline{e}_+(\underline{\mathcal{S}})}^{\underline{e}_-} = \epsilon_{\underline{\mathcal{S}}, \#\underline{e}_+(\underline{\mathcal{S}}), \underline{M}} \text{Tr}_{\underline{e}_-, \underline{e}_+}(\Phi_{\underline{\mathcal{S}}}),$$

where $\#\underline{e}_+(\underline{\mathcal{S}})$ is the quilted surface obtained by gluing the ends in \underline{e}_- to the corresponding ends in \underline{e}_+ . The algebraic trace $\text{Tr}_{\underline{e}_-, \underline{e}_+}$ is defined by the formula (8) but using the quilted cup and cap (a union of strips with Lagrangian boundary and seam conditions given by $\underline{L}_{\underline{e}_{\pm}}$ as for quilted Floer theory, but with two outgoing resp. incoming ends as in Figure 7) to define Φ_{\cup}, Φ_{\cap} . The sign $\epsilon_{\underline{\mathcal{S}}, \#\underline{e}_+(\underline{\mathcal{S}}), \underline{M}}$ is the gluing sign in Theorem 2.7 for the unquilted surface $\underline{\mathcal{S}}'$; it depends on the orderings of the boundary components and the dimensions of the entries of \underline{M} .

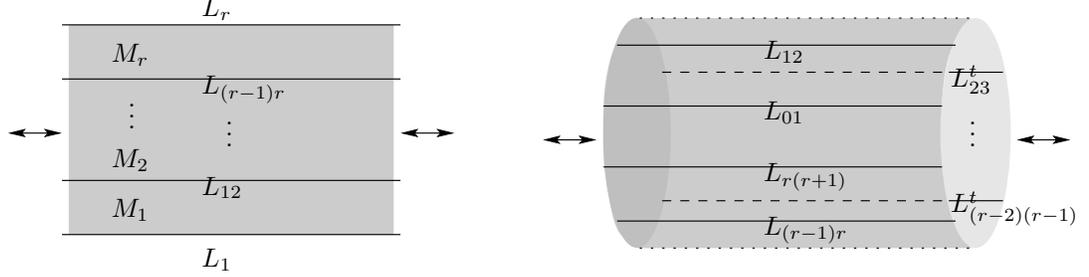

Figure 7. The quilted cup and cap for a noncyclic and a cyclic sequence of Lagrangian correspondences

4. Independence of quilt invariants

The purpose of this section is to prove the independence of the relative invariants arising from quilted surfaces.

Theorem 4.1. *Let \underline{S}_0 and \underline{S}_1 be two quilted surfaces of same combinatorial type as in Lemma 3.4, and with fixed widths \underline{d}_e at each quilted end. (We can view this as two different choices of complex structures \underline{j}_i for $i = 0, 1$, and seam maps $\underline{\phi}_i$ for $i = 0, 1$ on the same quilted surface \underline{S} with fixed strip-like ends.) Let $(\underline{K}_i, \underline{J}_i)$ for $i = 0, 1$ be regular choices of perturbation data on each \underline{S}_i with the same regular values on each strip-like end. Then the chain maps $C\Phi_{\underline{S}_0}$ and $C\Phi_{\underline{S}_1}$ induced by these choices descend to the same map $\Phi_{\underline{S}_0} = \Phi_{\underline{S}_1}$ on Floer cohomology.*

Proof. The key fact is that any two choices $(\underline{K}_i, \underline{J}_i, \underline{j}_i, \underline{\varphi}_i)$ for $i = 0, 1$, that are of fixed form over the strip-like ends, can be connected by a homotopy $(\underline{K}_\lambda, \underline{J}_\lambda, \underline{j}_\lambda, \underline{\varphi}_\lambda)_{\lambda \in [0, 1]}$. The homotopies of quilt data \underline{j}_λ and $\underline{\varphi}_\lambda$ are provided by Lemma 3.4. For the Hamiltonians \underline{K}_i we can use convex interpolation, and for the almost complex structures \underline{J}_i we employ the fact that the space of compatible almost complex structures is contractible. Given this homotopy, we can use the standard Floer homotopy argument:

Consider the universal moduli spaces consisting of pairs (λ, \underline{u}) of $\lambda \in [0, 1]$ and a solution \underline{u} with respect to the data $(\underline{K}_\lambda, \underline{J}_\lambda, \underline{j}_\lambda, \underline{\varphi}_\lambda)$. For a generic homotopy \underline{J}_λ , these are smooth manifolds. Their 0-dimensional components can be oriented and counted to define a map $C\Psi : \otimes_{\underline{e} \in \mathcal{E}_-(\underline{S})} CF(\underline{L}_{\underline{e}}) \rightarrow \otimes_{\underline{e} \in \mathcal{E}_+(\underline{S})} CF(\underline{L}_{\underline{e}})$. The 1-dimensional component has boundaries corresponding to the solutions contributing to $C\Phi_{\underline{S}_0}$ and $C\Phi_{\underline{S}_1}$ and ends corresponding to pairs of solutions contributing to $C\Psi$ and the boundary operators $\partial_\pm = \sum_{\underline{e} \in \mathcal{E}_\pm} \partial_{\underline{e}}$ in the Floer complexes for the ends. (Sphere and disk bubbling is excluded by monotonicity in 0- and 1-dimensional moduli spaces.) Counting these with orientations proves $C\Phi_{\underline{S}_0} - C\Phi_{\underline{S}_1} = \partial_+ \circ C\Psi + C\Psi \circ \partial_-$, i.e. $C\Psi$ defines a chain homotopy between $C\Phi_{\underline{S}_0}$ and $C\Phi_{\underline{S}_1}$, and hence $\Phi_{\underline{S}_0} = \Phi_{\underline{S}_1}$ on cohomology. See [12, Chapter 5.2] for the detailed construction. The orientations are given by the orientation of the determinant line bundles constructed in [20] plus a (first) \mathbb{R} -factor for the $[0, 1]$ -variable. The gluing of orientations is the same as in [20], and the signs for $C\Phi_{\underline{S}_i}$ arise from the boundary orientation of $\partial[0, 1] = \{0\}^- \cup \{1\}$. \square

Theorem 4.2. *The maps $\Phi_{\underline{S}}$ are in fact relative invariants, depending only on the combinatorial structure of the quilted surface \underline{S} . More precisely, for different choices ($i = 0, 1$) of strip-like ends, complex structures \underline{j}_i , seam maps $\underline{\varphi}_i$, and perturbation data $(\underline{K}_i, \underline{J}_i)$, we have $\Psi_+ \circ \Phi_{\underline{S}_0} \circ \Psi_- = \Phi_{\underline{S}_1}$. Here $\Psi_\pm = \otimes_{\underline{e} \in \mathcal{E}_\pm} \Psi_{\underline{e}}$, where $\Psi_{\underline{e}} : HF(\underline{L}_{\underline{e}})^0 \rightarrow HF(\underline{L}_{\underline{e}})^1$ for $\underline{e} \in \mathcal{E}^+$ resp. $\Psi_{\underline{e}} : HF(\underline{L}_{\underline{e}})^1 \rightarrow HF(\underline{L}_{\underline{e}})^0$ for $\underline{e} \in \mathcal{E}^-$ are the isomorphisms from [19] between the Floer cohomologies for the different widths and perturbation data on the end \underline{e} induced by $(\underline{K}_i, \underline{J}_i)$.*

Proof. Each $\Psi_{\underline{e}}$ is the relative invariant given by a quilted cylinder $\underline{Z}_{01}^{\underline{e}}$ resp. $\underline{Z}_{10}^{\underline{e}}$ interpolating between the widths and perturbation data $(\underline{\delta}_{\underline{e}}, \underline{H}_{\underline{e}}, \underline{J}_{\underline{e}})^i$ given from the quilted surfaces and perturbation data for $i = 0, 1$. By Theorem 3.13 (where the sign is positive) the composition $\Psi_+ \circ \Phi_{\underline{S}_0} \circ \Psi_- = \Phi_{\underline{S}'_1}$ is given by the relative invariant for the glued surface $\underline{S}'_1 = (\sqcup_{\underline{e} \in \mathcal{E}^+} \underline{Z}_{01}^{\underline{e}}) \# \underline{S}_0 \# (\sqcup_{\underline{e} \in \mathcal{E}^-} \underline{Z}_{10}^{\underline{e}})$. Now the widths and perturbations induced on the ends are the same for the quilted surfaces \underline{S}_1 and \underline{S}'_1 , hence Theorem 4.1 proves the identity $\Phi_{\underline{S}_1} = \Phi_{\underline{S}'_1}$. \square

5. Geometric composition and quilt invariants

Consider a quilted surface \underline{S} containing a patch S_{ℓ_1} that is diffeomorphic to $\mathbb{R} \times [0, 1]$ and attached via seams $\sigma_{01} = \{(\ell_0, I_0), (\ell_1, \mathbb{R} \times \{0\})\}$ and $\sigma_{12} = \{(\ell_1, \mathbb{R} \times \{1\}), (\ell_2, I_2)\}$ to other surfaces S_{ℓ_0}, S_{ℓ_2} . (The latter are necessarily different from S_{ℓ_1} , but we might have $\ell_0 = \ell_2$.) We can allow one but not both of these seams to be replaced by a boundary component, $(\ell_1, \mathbb{R} \times \{0\}) \in \mathcal{B}$ or $(\ell_1, \mathbb{R} \times \{1\}) \in \mathcal{B}$. In that case we set $M_{\ell_0} = \{\text{pt}\}$ resp. $M_{\ell_2} = \{\text{pt}\}$.

Let \mathcal{L} be Lagrangian boundary and seam conditions for \underline{S} and suppose that the Lagrangian correspondences $L_{\sigma_{01}} \subset M_{\ell_0}^- \times M_{\ell_1}$, $L_{\sigma_{12}} \subset M_{\ell_1}^- \times M_{\ell_2}$ associated to the boundary components of S_{ℓ_1} are such that $L_{\sigma_{01}} \circ L_{\sigma_{12}}$ is smooth and embedded by projection into $M_{\ell_0}^- \times M_{\ell_2}$. Let \underline{S}' denote the quilted surface obtained by removing the patch S_{ℓ_1} and corresponding seams and replacing it by a new seam $\sigma_{02} := \{(\ell_0, I_0), (\ell_2, I_2)\}$ with seam map $\varphi_{\sigma_{02}} := \varphi_{\sigma_{12}} \circ \varphi_{\sigma_{01}} : I_0 \xrightarrow{\sim} I_2$. We define Lagrangian boundary conditions \mathcal{L}' for \underline{S}' by $L_{\sigma_{02}} := L_{\sigma_{01}} \circ L_{\sigma_{12}}$. In this setting we have a canonical identification of Floer chain groups attached to the ends

$$(19) \quad CF(\underline{L}_{\underline{e}}) \xrightarrow{\sim} CF(\underline{L}'_{\underline{e}})$$

as in [19] for every $\underline{e} \in \mathcal{E}(\underline{S}) \cong \mathcal{E}(\underline{S}')$. Consider the relative invariants $\Phi_{\underline{S}}$ and $\Phi_{\underline{S}'}$ defined in Section 3.

Theorem 5.1. *Suppose that all symplectic manifolds in \underline{M} satisfy (M1-2) with the same monotonicity constant, all Lagrangians in \mathcal{L} satisfy (L1-3), and \mathcal{L} is monotone and relative spin. Assume moreover that $L_{\sigma_{01}} \circ L_{\sigma_{12}}$ is embedded (in the sense defined in the introduction). Then (19) induces isomorphisms in Floer cohomology*

$$\Psi_{\underline{e}} : HF(\underline{L}_{\underline{e}}) \rightarrow HF(\underline{L}'_{\underline{e}})$$

and furthermore these maps intertwine with the relative invariants:

$$\Phi_{\underline{S}'} \circ \left(\bigotimes_{\underline{e} \in \mathcal{E}^-} \Psi_{\underline{e}} \right) = \left(\bigotimes_{\underline{e} \in \mathcal{E}^+} \Psi_{\underline{e}} \right) \circ \Phi_{\underline{S}} [n_{\ell_1} d].$$

Here $2n_{\ell_1}$ is the dimension of M_{ℓ_1} in the shift of degree $[n_{\ell_1} d]$, and $d = 1, 0$, or -1 according to whether the removed strip S_{ℓ_1} has two outgoing ends, one in- and one outgoing, or two incoming ends.

Note that Theorem 5.1 does not assume $L_{\sigma_{01}} \circ L_{\sigma_{12}}$ to satisfy (L1-3) or monotonicity of \mathcal{L}' . (L2) holds automatically for the geometric composition, and monotonicity of \mathcal{L}' follows directly from that of \mathcal{L} since any quilted map in Definition 3.6 for \mathcal{L}' can be lifted to one for \mathcal{L} with the same area and index. Similarly, all cyclic sequences $\underline{L}'_{\underline{e}}$ are automatically monotone; as a consequence (L1) holds for $L_{\sigma_{01}} \circ L_{\sigma_{12}}$, and as explained in [19] the Floer cohomologies are well defined, even if (L3) may not hold for $L_{\sigma_{01}} \circ L_{\sigma_{12}}$.

Example 5.2. To see the necessity of the degree shift in a simple example, suppose that $\underline{S} = (S)$ is the disk with two incoming ends, and $\Phi_{\underline{S}}$ the corresponding relative invariant described in (5). Suppose that L^0, L^1 intersect in a single point x . Then the theorem above applies, \underline{S}' is empty, $\Phi_{\underline{S}'}$ is the trivial invariant, and $\Psi_{\underline{e}_-}$ maps $\langle x \rangle \otimes \langle x \rangle \mapsto 1$. On the other hand, $\Phi_{\underline{S}}$ is the duality pairing, which has degree $-n$.

On the level of chain complexes the maps Ψ_ϵ are simply the identity. Therefore it suffices to show that the maps $C\Phi_{\underline{S}}$ and $C\Phi_{\underline{S}'}[d_k n_k]$ are equal for sufficiently small width. See (15) for an explanation of the grading shift. The bijection between pseudoholomorphic quilts follows from essentially the same degeneration argument in [17] which was also used in [19]. However, in this case the adjoint of the linearized operator is honestly surjective. (There is no translational symmetry, so elements of the zero-dimensional moduli space have linearized operators of index zero, not one.) The surfaces to the left and right of the shrinking strip are arbitrary quilted surfaces, but this is of no relevance in the proof. It suffices to work with the uniformizing neighbourhoods $\mathbb{R} \times (-\epsilon, 0] \hookrightarrow S_{\ell_0}$ and $\mathbb{R} \times [0, \epsilon) \hookrightarrow S_{\ell_2}$ in which the seam maps are the identity on \mathbb{R} .

Remark 5.3. In [17] a strip degeneration argument is used to establish a canonical isomorphism

$$(20) \quad HF(L_0, L_{01}, L_{12}, L_2) \longrightarrow HF(L_0, L_{02}, L_2)$$

for embedded composition of monotone Lagrangians. The natural alternative approach to defining an isomorphism, or even just a homomorphism is to try and interpolate the middle strip to zero width in the relative invariant that is used in [19] to prove the independence of $HF(L_0, L_{01}, L_{12}, L_2)$ from the choice of width $\delta_1 > 0$. The resulting quilted surface might look as indicated on the left in Figure 8. This approach was pioneered by Matthias Schwarz and might be realized as a “jumping boundary condition” as investigated in [1]. However, this analytic setup is at present restricted to a highly specialized class of Lagrangians and almost complex structures. In essence, this approach would construct a canonical element of the Floer homology $HF(L_{02}, (L_{01}, L_{12}))$ associated to the three seams coming together. Our approach also induces such a canonical element, given by the identity $1_{L_{02}} \in HF(L_{02}, L_{02})$ and the strip shrinking isomorphism to $HF(L_{02}, (L_{01}, L_{12}))$. So we replace the picture of seams coming together by one where the seams corresponding to L_{01} , L_{12} , L_{02} run into an infinite cylindrical end, as on the right in Figure 8, where the inner circle is meant to represent a cylindrical end. This picture defines a relative invariant

$$\Upsilon : HF(L_{02}, (L_{01}, L_{12})) \otimes HF(L_0, L_{01}, L_{12}, L_2) \rightarrow HF(L_0, L_{02}, L_2).$$

Now the isomorphism (20) can then alternatively be described by $\Upsilon(T, \cdot)$, where $T \in HF(L_{02}, (L_{01}, L_{12}))$ is the morphism corresponding to the identity $1_{L_{02}} \in HF(L_{02}, L_{02})$, see Corollary 5.4.

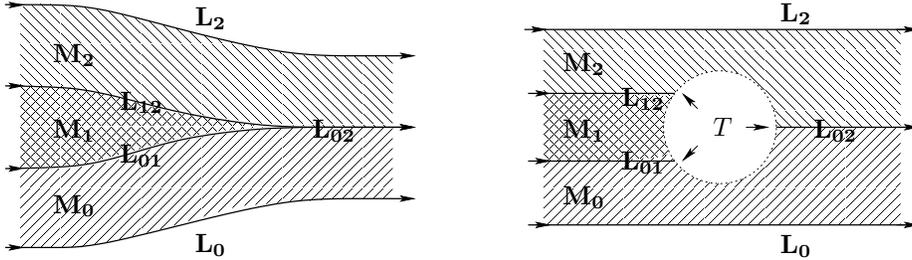

Figure 8. Alternative approaches to a homomorphism

As a first application of Theorem 5.1 we prove the claim of Remark 5.3. For that purpose we denote by

$$\begin{aligned} \Psi &: HF(L_0, L_{01}, L_{12}, L_2) \rightarrow HF(L_0, L_{02}, L_2), \\ \tilde{\Psi} &: HF(L_{02}, (L_{01}, L_{12})) \rightarrow HF(L_{02}, L_{02}) \end{aligned}$$

the isomorphisms (1) from [19]. Then we have the following alternative description of Ψ (which a priori depends on L_0 and L_2) in terms of $\tilde{\Psi}$ and the identity morphism $1_{L_{02}} \in HF(L_{02}, L_{02})$, defined in [18].

Corollary 5.4. *Let*

$$\Upsilon : HF(L_{02}, (L_{01}, L_{12})) \otimes HF(L_0, L_{01}, L_{12}, L_2) \rightarrow HF(L_0, L_{02}, L_2)$$

denote the relative invariant associated to the quilted surface on the right in Figure 8. Then we have for all $f \in HF(L_0, L_{01}, L_{12}, L_2)$

$$\Psi(f) = \Upsilon(\tilde{\Psi}^{-1}(1_{L_{02}}) \otimes f).$$

Moreover, in the notation of [18], we have $\Upsilon(T \otimes f) = \Phi_T(L_0) \circ f$, where $\Phi_T : \Phi(L_{02}) \rightarrow \Phi(L_{01}, L_{12})$ is a natural transformation of functors associated to any $T \in HF(L_{02}, (L_{01}, L_{12}))$.

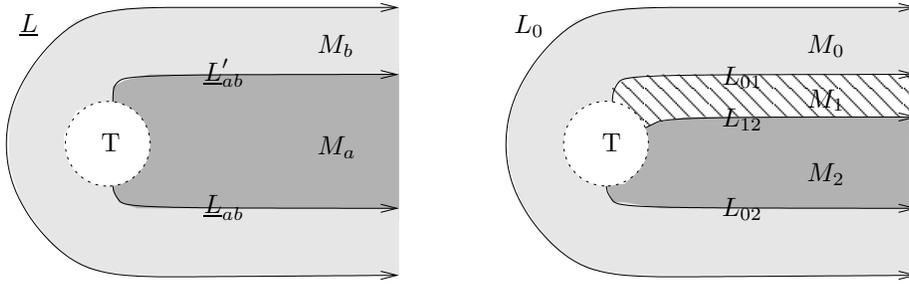

Figure 9. Natural transformation associated to a Floer cohomology class: General case from [18] and the present special case.

Proof. We apply Theorem 5.1 to $\Upsilon = \Phi_{\underline{S}}$, where the quilted surface \underline{S} contains one simple strip in M_1 . (The other surfaces are triangles.) This implies $\Upsilon(T \otimes f) = \Phi_{\underline{S}'}(\tilde{\Psi}(T) \otimes \Psi(f))$, where the quilted surface \underline{S}' is obtained by replacing this strip with a seam condition in $L_{01} \circ L_{12} = L_{02}$. To calculate this for $\tilde{\Psi}(T) = 1_{L_{02}}$ we use the gluing formula (18) to obtain $\Upsilon(\tilde{\Psi}^{-1}(1_{L_{02}}) \otimes f) = \Phi_{\underline{S}''}(\Psi(f))$, where \underline{S}'' is the surface that is obtained by gluing the quilted cap of Figure 7 into \underline{S}' . Since \underline{S}'' is a simple double strip (with seam condition L_{02} and boundary conditions L_0, L_2), and we do not quotient out by translation, the relative invariant $\Phi_{\underline{S}''}$ is the identity, as in Example 2.5. This proves the first claim.

The second claim follows from a deformation of the quilt \underline{S} to the glued quilt that corresponds, by (18), to the composition of the natural transformation $T \mapsto \Phi_T(L_0) \in HF((L_0, L_{02}), (L_0, L_{01}, L_{12}))$ (given by the quilt in Figure 9) with the pair of pants product from $HF((L_0, L_{02}), (L_0, L_{01}, L_{12})) \otimes HF((L_0, L_{01}, L_{12}), L_2)$ to $HF((L_0, L_{02}), L_2)$ defined in [18]. Figure 10 gives a picture summary of these arguments. \square

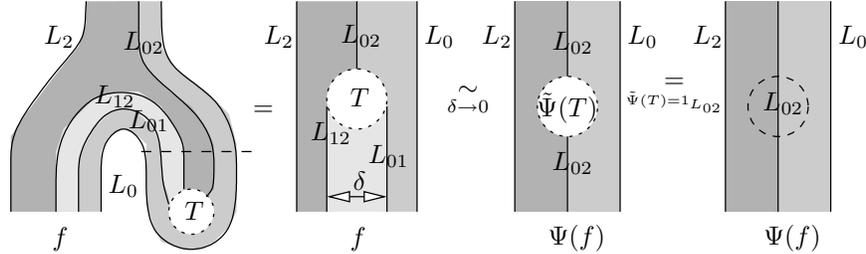

Figure 10. Proof by pretty picture

6. Application: Morphism between quantum homologies

Given a Lagrangian correspondence $L_{01} \subset M_0^- \times M_1$ a natural question is whether – analogous to a symplectomorphism or certain birational equivalences as in [4] – it induces a ring morphism $\Phi(L_{01}) : HF(\Delta_{M_0}) \rightarrow HF(\Delta_{M_1})$ between the quantum homologies. A quilted cylinder indeed defines a morphism, which however generally does not intertwine the product structures. Conjecturally, it is a Floer theoretic equivalent of the slant product⁸ on cohomology $H^*(M_0) \rightarrow H^*(M_1)$ with the Poincaré dual of the fundamental class of L_{01} . Even in this classical case, one generally only obtains a ring homomorphism if L_{01} is the graph of a continuous map. Moreover, both the classical and Floer theoretic morphism will shift the grading unless $\dim M_0 = \dim M_1$. While Albers-Schwarz are working on refined versions of this morphism, we here use the framework of quilts to clarify the algebraic structure and behaviour under geometric composition of Lagrangian correspondences.

Remark 6.1. The quilted Floer cohomology $HF(\Delta_M)$ of the diagonal by definition is nothing else but Hamiltonian periodic Floer cohomology $HF(M) = HF(H)$ for a generic Hamiltonian $H : S^1 \times M \rightarrow \mathbb{R}$. The latter is naturally isomorphic to the quantum homology of M , see [9].

Theorem 6.2. *Let $L_{01} \subset M_0^- \times M_1$ be a Lagrangian correspondence between symplectic manifolds M_0, M_1 satisfying (M1–2) and (L1–2), and assume that the pair (L_{01}, L_{01}) is monotone for Floer theory.⁹ Then the quilted cylinder in Figure 11 defines a natural map*

$$\Phi_{L_{01}} : HF(\Delta_{M_0}) \rightarrow HF(\Delta_{M_1}).$$

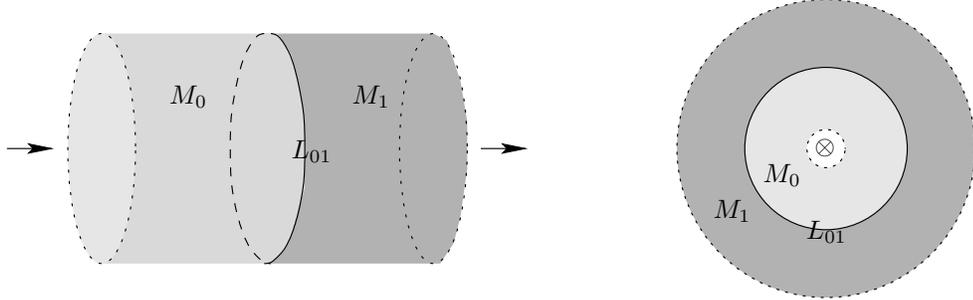

Figure 11. Two views of the quilted cylinder defining $\Phi_{L_{01}}$. It consists of two half cylinders (the domains of maps to M_0 and M_1 – in this order to fix orientations), with a seam identifying the two circle boundaries (giving rise to a seam condition in L_{01}). Arrows indicate incoming and outgoing ends, the outside circle is always an outgoing end, and \otimes indicates incoming ends.

Moreover, this map factors $\Phi_{L_{01}} = \Theta_{L_{01}} \circ \Psi_{L_{01}}$ according to Figure 12 into maps

$$\Psi_{L_{01}} : HF(\Delta_{M_0}) \rightarrow HF(L_{01}, L_{01}), \quad \Theta_{L_{01}} : HF(L_{01}, L_{01}) \rightarrow HF(\Delta_{M_1}).$$

Here $\Psi_{L_{01}}$ is a ring morphism, whereas $\Theta_{L_{01}}$ satisfies

$$\Theta_{L_{01}}(x \circ y) = \Theta_{L_{01}}(x) \circ \Theta_{L_{01}}(y) = x \circ T_{L_{01}} \circ y$$

⁸On de Rham cohomology, the product $\Omega^k(M_0 \times M_1) \times \Omega^\ell(M_0) \rightarrow \Omega^{k+\ell-\dim(M_0)}(M_1)$ is given by integration over one factor, $(\eta, \alpha) \mapsto \int_{M_0} (\eta \wedge \alpha)$.

⁹The latter monotonicity requires an action-index relation for annuli in $M_0^- \times M_1$ with boundaries on L_{01} . All these monotonicity assumptions can be replaced by any other set of assumptions which ensure that all Floer homologies involved are well defined and disk bubbles on L_{01} cannot appear in 0- or 1-dimensional moduli spaces of holomorphic quilts.

for all $x, y \in HF(L_{01}, L_{01})$ and a fixed element $T_{L_{01}} \in HF(L_{01}^t, L_{01}, L_{01}^t, L_{01})$ that only depends on L_{01} . For the latter we assume monotonicity of the sequence $(L_{01}^t, L_{01}, L_{01}^t, L_{01})$ and the composition¹⁰ on the right hand side as well as $T_{L_{01}}$ are defined by relative quilt invariants as indicated in Figure 15.

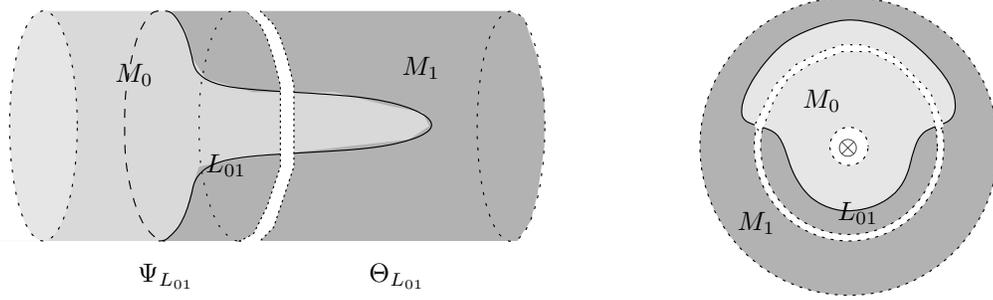

Figure 12. Two views of the splitting $\Phi_{L_{01}} = \Theta_{L_{01}} \circ \Psi_{L_{01}}$. The quilted surface defining $\Psi_{L_{01}}$ consists of a disk labeled M_0 with one interior puncture (incoming end) and one boundary puncture (outgoing end), a disk labeled M_1 with one boundary puncture (outgoing end), and a seam labeled L_{01} identifying the two boundary components. The quilted surface defining $\Theta_{L_{01}}$ is the same with M_0, M_1 and incoming/outgoing ends interchanged.

Remark 6.3. As pointed out by the referee, the composition of pull-back $\Psi_{L_{01}}$ with push-forward $\Theta_{L_{01}}$ is not the one that classically preserves multiplicative structures. However, the classical projection formula $f_!(x \cup f^*(y)) = f_!(x) \cup y$ relating multiplicative structures under pull-back f^* and push-forward $f_!$ has a Floer theoretic version as follows.

We view $\Psi_{L_{01}}^T : HF(\Delta_{M_1}) \rightarrow HF(L_{01}^T, L_{01}^T) \cong HF(L_{01}, L_{01})$ as push-back and $\Theta_{L_{01}}$ again as push-forward, then the Floer theoretic projection formula holds:

$$\Theta_{L_{01}}(x \circ \Psi_{L_{01}}^T(y)) = \Theta_{L_{01}}(x) \circ y \quad \forall x \in HF(L_{01}, L_{01}), y \in HF(\Delta_{M_1}).$$

The proof of this identity is a recommended exercise in applying the gluing and deformation laws for holomorphic quilts. Hint: Read the proof of Theorem 6.2 for very similar arguments.

Remark 6.4. a) One can check with Remark 3.10 that the degree (modulo the minimal Maslov number $N_{L_{01}}$) of $\Phi_{L_{01}}$ agrees with the degree $d_{L_{01}} := \frac{1}{2}(\dim(M_1) - \dim(M_0))$ of the slant product. Indeed, the outgoing cylindrical end counts as $\#\mathcal{E}_+(S_1) = 2$. To see this, alternatively add a seam connecting the outgoing end to itself, labeled with the diagonal of M_1 . Then we have two patches mapping to M_1 with one outgoing end each and total Euler characteristic 1. b) By concatenating the morphism $\Phi_{L_{01}} : HF(\Delta_{M_0}) \rightarrow HF(\Delta_{M_1})$ with the PSS-isomorphisms $H_*(M_0; \mathbb{Z}) \rightarrow HF(\Delta_{M_0})$ and $HF(\Delta_{M_1}) \rightarrow H_*(M_1; \mathbb{Z})$ from [9] one can see why this should be the slant product: The concatenation is a map $H_*(M_0; \mathbb{Z}) \rightarrow H_*(M_1; \mathbb{Z})$ on Morse homology. Between two critical points $x_0 \in \text{Crit}(f_0) \subset M_0$ and $x_1 \in \text{Crit}(f_1) \subset M_1$ the coefficient of the map is given by counting holomorphic disks in $\pi_2(M_0^- \times M_1, L_{01})$ with a marked point in the interior mapping to the product $W^u(x_0, f_0) \times W^s(x_1, f_1)$ of unstable and stable manifolds. Here the holomorphic curve equation is perturbed by Hamiltonian vector fields and uses almost

¹⁰Strictly speaking, the composition is defined by viewing x and y as elements in the trivially isomorphic quilted Floer cohomologies $x \in HF(\Delta_{M_1}, (L_{01}^t, L_{01}))$ and $y \in HF((L_{01}^t, L_{01}), \Delta_{M_1})$ – here in the notation for the pair of generalized Lagrangian correspondences Δ_{M_1} and (L_{01}^t, L_{01}) from M_1 to M_1 . Then $x \circ T_{L_{01}} \circ y$ is the composition constructed in [18] in the refined Donaldson-Fukaya category $\text{Don}^\#(M_1, M_1)$ of correspondences from M_1 to M_1 . In fact, it is the composition of morphisms $\Delta_{M_1} \xrightarrow{x} (L_{01}^t, L_{01}) \xrightarrow{T_{L_{01}}} (L_{01}^t, L_{01}) \xrightarrow{y} \Delta_{M_1}$, taking values in $HF(\Delta_{M_1}, \Delta_{M_1})$, which again is trivially identified with $HF(\Delta_{M_1})$.

complex structures parametrized by the disk. One can homotope the Hamiltonian perturbations to zero, not affecting the map on homology.

Next, recall that due to the grading ambiguity of $N_{L_{01}}$ on L_{01} , all gradings on Floer and Morse homology above should be taken modulo $N_{L_{01}}$. Hence, restricted to a fixed grading $k = 0, \dots, \dim M_0$ the morphism $\Phi_{L_{01}}$ induces a map

$$\Phi_{L_{01}}^k : H_k(M_0; \mathbb{Z}) \rightarrow \bigoplus_{\ell \in \mathbb{N}_0} H_{k+d_{L_{01}}+\ell N_{L_{01}}}(M_1; \mathbb{Z}).$$

Here the contributions for each $\ell \in \mathbb{N}_0$ arise from holomorphic disks as above, of Maslov index $\ell N_{L_{01}}$. For the leading part of this map, the contributions for $\ell = 0$ are those of zero energy, that is exactly the constant maps to L_{01} . This is essentially the same calculation as in [3, Remark 1.3].

With this one can check that the leading part of $\Phi_{L_{01}}^k$ is indeed the Morse theoretic version of the slant product. If one could moreover achieve transversality with S^1 -invariant almost complex structures, then (w.l.o.g. putting the marked point in the center of the disk) the only isolated solutions would be constant disks. This would identify $\Phi_{L_{01}}$ with a Morse theoretic version of the slant product.

Proof of Theorem 6.2. Our assumptions guarantee that Theorem 3.9 applies to the moduli spaces of pseudoholomorphic maps from the quilted cylinder \underline{S} indicated in Figure 11 to M_0 and M_1 , with seam condition on L_{01} . (In fact, doubling this quilted surface exactly amounts to an annulus mapping to $M_0^- \times M_1$ with both boundary conditions in L_{01} . Monotonicity for that surface is given by the monotonicity for Floer theory.) Hence these moduli spaces define a map $\Phi_{L_{01}}$ on Floer cohomology as in (14). Strictly speaking, the cyclic generalized correspondences associated to the two ends of \underline{S} are the empty sequences – as trivial correspondence from M_i to M_i . However, quilted Floer cohomology for these is trivially identified with quilted $HF(\Delta_{M_i})$, which is also trivially identified with the usual Floer cohomology for the pair $HF(\Delta_{M_i}, \Delta_{M_i})$. All of these count pseudoholomorphic cylinders in M_i with a Hamiltonian perturbation.

The map $\Phi_{L_{01}} : HF(\Delta_{M_0}) \rightarrow HF(\Delta_{M_1})$ is natural in the sense that, by Theorems 4.1 and 4.2 it is independent of the choice of complex structures and seam maps on \underline{S} , almost complex structures, and Hamiltonian perturbations. The map is hence determined purely by L_{01} and the chosen combinatorial structure of the quilted cylinder.

Next, the splitting $\Phi_{L_{01}} = \Theta_{L_{01}} \circ \Psi_{L_{01}}$ follows from Theorem 3.13 applied to the gluing of quilted surfaces indicated in Figure 12. The gluing sign is $+1$ since there are no further incoming ends (see Theorem 2.8 for the sign), and if we fix the order of patches for $\Theta_{L_{01}}$ as induced by $\Phi_{L_{01}}$. (For $\Psi_{L_{01}}$ the order of patches is irrelevant for orientations since each patch has even deficiency – see Remark 3.11.) Monotonicity for these quilts as well as the pair of pants quilts below follows from the monotonicity for disks and spheres ensured by (M2) and (L2) since all Hamiltonian orbits resp. Hamiltonian chords generating the Floer cohomologies can be contracted.¹¹ To establish the interaction of these maps with the product structures recall that the product on $HF(\Delta_{M_i})$ is the relative invariant $\Phi_{S_{pop}}$ defined (see Section 2) by the pair of pants surface (a sphere with two incoming and one outgoing puncture). As usual, we draw this surface as a disk with two inner disks removed – their boundaries are the incoming ends, while the outer circle is the outgoing end. The product on $HF(L_{01}, L_{01})$ is in the setting of Section 2 given by the half pair of pants surface (a disk with two incoming and one outgoing puncture on the boundary). However, since the disk maps to $M_0^- \times M_1$, we can also view it as two disks mapping to M_0 and M_1 respectively (where one carries the opposite orientation), with three boundary punctures each, all three boundary components identified and satisfying the seam condition in L_{01} . Viewed as quilted surface, this is a pair of pants surface

¹¹Strictly speaking, we either work with C^1 -small Hamiltonian perturbations whose orbits resp. chords are automatically contractible, or we restrict the map to contractible orbits resp. chords. The isomorphism of Floer cohomologies for different Hamiltonian perturbations automatically maps contractible to contractible generator, and hence shows that the noncontractible generators do in fact not contribute to the cohomology.

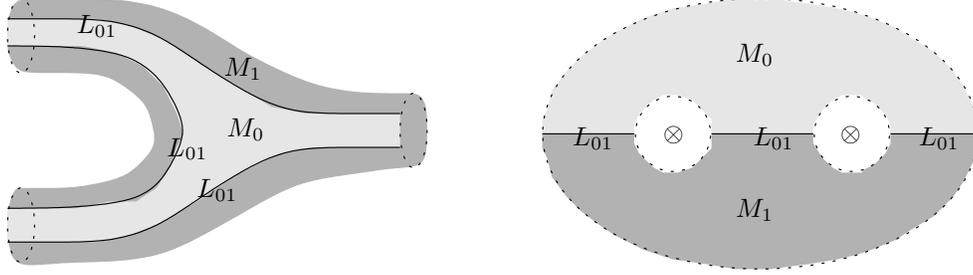

Figure 13. Two views of the quilted pair of pants defining the product on $HF(L_{01}, L_{01})$

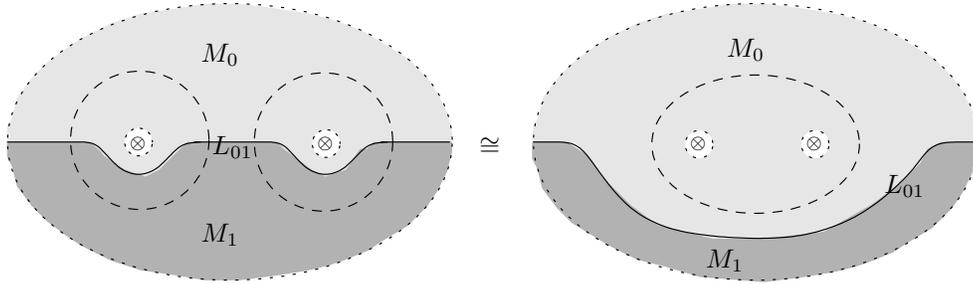

Figure 14. Gluing and homotopy of quilts proving that $\Psi_{L_{01}}$ is a ring homomorphism

on which three seams connect each pair of ends, see Figure 13. If we view $HF(L_{01}, L_{01})$ as quilted Floer cohomology for the sequence (L_{01}, L_{01}^t) , then the relative invariant $\Phi_{\underline{S}_{pop}}$ associated to this quilted pair of pants is exactly the product. We can hence use this definition to calculate for all $f, g \in HF(M_0)$

$$\Psi_{L_{01}}(f) \circ \Psi_{L_{01}}(g) = (\Phi_{\underline{S}_{pop}} \circ (\Psi_{L_{01}} \otimes \Psi_{L_{01}}))(f, g) = (\Psi_{L_{01}} \circ \Phi_{\underline{S}_{pop}})(f, g) = \Psi_{L_{01}}(f \circ g).$$

Here the first and third equality is by definition. The middle identity $\Phi_{\underline{S}_{pop}} \circ (\Psi_{L_{01}} \otimes \Psi_{L_{01}}) = \Psi_{L_{01}} \circ \Phi_{\underline{S}_{pop}}$ follows from gluing the quilted surfaces in different order (using Theorem 3.13) and homotoping (using Theorem 4.1) between the two resulting quilted pair of pants surfaces that both have one seam connecting the outgoing end to itself and the two incoming ends on M_0 , see Figure 14. The gluing signs are +1, in the first case since the incoming patches have one boundary component, in the second case since the outgoing patch has only one incoming end, c.f. Theorem 2.8. This proves that $\Psi_{L_{01}}$ is indeed a ring morphism.

Similarly, we can write for all $x, y \in HF(L_{01}, L_{01})$

$$\begin{aligned} \Theta_{L_{01}}(x) \circ \Theta_{L_{01}}(y) - \Theta_{L_{01}}(x \circ y) &= (\Phi_{\underline{S}_{pop}} \circ (\Theta_{L_{01}} \otimes \Theta_{L_{01}}) - \Theta_{L_{01}} \circ \Phi_{\underline{S}_{pop}})(x, y) \\ &= (\Phi_{\underline{S}_{3p}} - \Phi_{\underline{S}_{2p}})(x, y) \\ &= (\Phi_{\underline{S}_{3comp}} \circ (\text{Id} \otimes (\Phi_{\underline{S}_1} - \Phi_{\underline{S}_0}) \otimes \text{Id}))(x, y) \\ &= \Phi_{\underline{S}_{3comp}}(x, T_{L_{01}} \circ y) = x \circ T_{L_{01}} \circ y. \end{aligned}$$

Again, the first equality is by definition and the second identity follows from the gluing Theorem 3.13. In this case, however, we obtain two different quilted surfaces: The first composition results in the quilted pair of pants \underline{S}_{3p} with two seams between three patches (and the M_0 -patches ordered according to order of incoming ends), whereas the second composition results in the quilted pair of pants \underline{S}_{2p} with two seams between two patches (with the M_0 -patch ordered before the M_1 -patch), see Figure 15. Again, the gluing signs are +1 since the incoming patches have one boundary component, c.f. Theorem 2.8. These two quilted surfaces are connected only by a 'singular homotopy' which lets

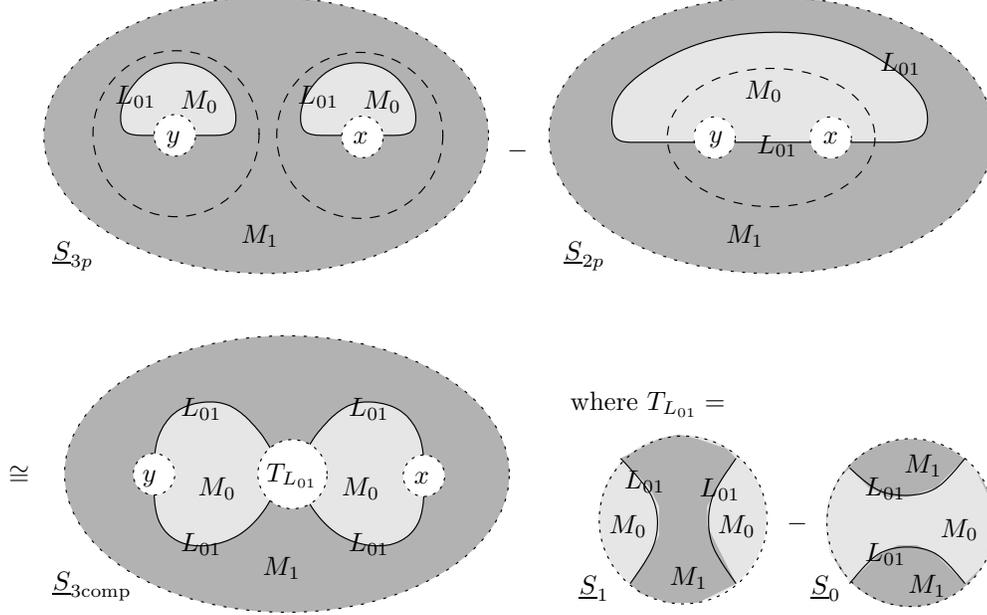

Figure 15. Manipulation of quilts proving the product identity for $\Theta_{L_{01}}$. Each of the two quilts \underline{S}_{3p} and \underline{S}_{2p} in the first row can also be obtained by gluing one of the two quilts \underline{S}_1 and \underline{S}_0 in the definition of $T_{L_{01}}$ into the middle end of the quilt \underline{S}_{3comp} in the second row.

the two seams intersect at a point and then connects them differently. Within our framework we can express this as follows: Both \underline{S}_{3p} and \underline{S}_{2p} are obtained from the same quilted surface \underline{S}_{3comp} (consisting of one M_1 disk with three boundary and one interior puncture and two M_0 disks with two boundary punctures) by gluing different quilted disks into the middle end (which has four seams ending in it, hence each disk must have two seams connecting these ends). (The induced ordering on \underline{S}_{3comp} has the two M_0 -patches according to incoming ends before the M_1 -patch.) To obtain \underline{S}_{3p} we glue in the quilted disk \underline{S}_1 which has one M_1 strip connecting different ends of the M_1 patch in \underline{S}_{3comp} to produce an annulus, which is the M_1 patch in \underline{S}_{3p} . To obtain \underline{S}_{2p} we use the quilted disk \underline{S}_0 with one M_0 strip connecting the two M_0 patches in \underline{S}_{3comp} to provide a single M_0 patch in \underline{S}_{2p} . (The ordering of patches on \underline{S}_1 and \underline{S}_0 is immaterial since only the middle patch in each has odd deficiency. The gluing signs are $+1$ for each patch since the incoming patches have one boundary component. Note however that the middle patch gets glued at two ends. For \underline{S}_0 these are two composition gluings, joining different surfaces, but for \underline{S}_1 the second gluing joins a surface to itself. Signs for this gluing are discussed in [20].) The smooth part of these homotopies (using Theorem 4.1) together with again the gluing Theorem 3.13 prove the third identity. Since both quilted disks \underline{S}_1 and \underline{S}_0 just have an outgoing end, they define an element of quilted Floer cohomology

$$T_{L_{01}} := \Phi_{\underline{S}_1} - \Phi_{\underline{S}_0} \in HF(L_{01}^t, L_{01}, L_{01}^t, L_{01}).$$

(Here we need a separate (e.g. monotonicity) assumption to ensure the Floer homology is well defined. Then the quilts $\underline{S}_0, \underline{S}_1$ are monotone since their double can be glued and homotoped to an annulus with boundaries on L_{01} . By a similar homotopy, or using the gluing identities, we deduce monotonicity for \underline{S}_{3comp} .) With this definition, the fourth identity again is just by convention, and since we define the triple composition $x \circ T \circ y$ by the relative quilt invariant

$$\Phi_{\underline{S}_{3comp}} : HF(L_{01}, L_{01}) \otimes HF(L_{01}^t, L_{01}, L_{01}^t, L_{01}) \otimes HF(L_{01}, L_{01}) \rightarrow HF(\Delta_{M_1}),$$

this proves the product identity for $\Theta_{L_{01}}$. Finally, the quilted Floer cohomology class $T_{L_{01}}$ only depends on L_{01} and the (given) simple combinatorial type of the quilted surfaces \underline{S}_1 and \underline{S}_0 , by Theorems 4.1 and 4.2. \square

Unlike the previous theorem, which directly generalizes to any version of Floer cohomology with Novikov rings, virtual fundamental classes, or abstract deformations, the following “quantization commutes with composition” result requires the full strict monotonicity assumptions due to the potential figure eight bubbling described in [17].

Theorem 6.5. *Let $L_{01} \subset M_0^- \times M_1$ and $L_{12} \subset M_1^- \times M_2$ be Lagrangian correspondences satisfying (L1–2) between symplectic manifolds M_0, M_1, M_2 satisfying (M1–2) with a fixed monotonicity constant $\tau \geq 0$. Assume that both pairs (L_{01}, L_{01}) and (L_{12}, L_{12}) are monotone for Floer theory and that the geometric composition $L_{01} \circ L_{12}$ is embedded. Then*

$$\Phi_{L_{01}} \circ \Phi_{L_{12}} = \Phi_{L_{01} \circ L_{12}}.$$

Proof. While the geometric composition $L_{01} \circ L_{12}$ of two monotone Lagrangian correspondences may not automatically satisfy (L2), the monotonicity for Floer theory transfers to the geometric composition (see [19]), and then also implies (L2). Hence $L_{01} \circ L_{12}$ also satisfies the assumptions of Theorem 6.2 and $\Phi_{L_{01} \circ L_{12}}$ is well defined.

Now, by the gluing Theorem 3.13 (with +1 sign since no further incoming ends are involved) we have $\Phi_{L_{01}} \circ \Phi_{L_{12}} = \Phi_{(L_{01}, L_{12})}$, where the latter is the relative quilt invariant associated to the quilted surface on the left in Figure 16: two disks with interior puncture mapping to M_0 resp. M_2 , one annulus A without puncture mapping to M_1 , and two seams connecting the boundary of each disk to one of the annulus boundary components, and with seam condition in L_{01} and L_{12} respectively. In the definition of $\Phi_{(L_{01}, L_{12})}$ we can pick any complex structure on (in particular) the annulus, e.g. $A = \mathbb{R}/\mathbb{Z} \times [0, \delta] \subset \mathbb{C}/\mathbb{Z}$ with the standard complex structure for any $\delta > 0$. For the other patches we pick the same complex structures and perturbations as some regular choice in the definition of $\Phi_{L_{01} \circ L_{12}}$. We claim that this provides regular moduli spaces for $\Phi_{(L_{01}, L_{12})}$ as well, and that the 0-dimensional spaces of solutions are in fact bijective to those for $\Phi_{L_{01} \circ L_{12}}$. For the proof of this bold claim we refer to [17], where the same analysis (just somewhat harder due to the noncompactness of the shrinking domain) is carried out in the case where A is replaced by a strip $\mathbb{R} \times [0, \delta]$ between other strips of fixed width. The crucial part of this proof is to exclude bubbling effects: As $\delta \rightarrow 0$, one may obtain sphere bubbles in M_0 , M_1 , or M_2 as well as disk bubbles in $(M_0^- \times M_1, L_{01})$, $(M_2^- \times M_2, L_{12})$, or $(M_0^- \times M_2, L_{01} \circ L_{12})$, and finally a novel type of bubble, called the “figure eight bubble”, see [17, 19] for details. For the latter we are currently lacking a removable singularity theorem, so cannot exclude it by reasons such as a trivial homotopy class of figure eight maps or high codimension (in fact, we expect cases where these bubbles appear generically). Our solution is to use the full power of the monotonicity assumption together with an (indirectly proven) energy quantization for the figure eight bubble: If it appears then the remaining main component is a holomorphic quilt contributing to $\Phi_{L_{01} \circ L_{12}}$ which has less energy than the index 0 solutions contributing to $\Phi_{(L_{01}, L_{12})}$. However, the energy for index 0 solutions is the same for both relative quilt invariants, so by strict monotonicity the remaining solution would have negative index – which is excluded by regularity of the moduli spaces. This proves the equality $\Phi_{(L_{01}, L_{12})} = \Phi_{L_{01} \circ L_{12}}$ and thus finishes the proof of the Theorem. \square
