Hartshorne, Chapter 1.5 Answers to exercises.

- 5.1a This is the tacnode. The singular points are the points with $x^2 = x^4 + y^4$, $2x = 4x^3$, and $4y^3 = 0$, so (at least in characteristic 0) the only singular point is (0,0).
- 5.1b This is the node; singular point is (0,0).
- 5.1c This is the cusp; singular point is (0,0).
- 5.1d This is the triple point; singular point is (0,0).
- 5.2 The singular points of f(x, y, z) = 0 are given by f = 0, $\frac{\partial f}{\partial x} = 0$, $\frac{\partial f}{\partial y} = 0$, and $\frac{\partial f}{\partial z} = 0$. 5.2a This is the pinch point; singular points are where $xy^2 = z^2$, $y^2 = 0$, 2xy = 0, and 2z = 0, which is the line y = z = 0.
- 5.2b This is the conical double point; singular points are where $x^2 + y^2 = z^2$, 2x = 0, 2y = 0, and 2z = 0, which is the point (0,0,0).
- 5.2c This is the double line; singular points are where $xy + x^3 + y^3 = 0$, $y + 3x^2 = 0$, $x + 3y^2 = 0$, and 0 = 0, which is the line x = y = 0.
- 5.3a If P is a point on Y then P is a nonsingular point of Y is equivalent to saying that one of $\frac{\partial f}{\partial x}$, $\frac{\partial f}{\partial y}$ are nonzero at P, which is equivalent to saying that f has a term of degree 1 in x and y, which is equivalent to saying that $\mu_P(Y) = 1$.
- 5.3b The singularities in 1a, 1b, and 1c have multiplicity 2, and 1d has multiplicity 3.
- 5.4a f and g both vanish at only a finite number of points, so we can find a polynomial h(y) which vanishes whenever f and g both vanish, so $h^n \in (f,g)$ for some n, so we can assume n=1. The submodules of $O_P/(f,g)$ correspond to ideals of O_P containing f and g, so it is sufficient to show that k[x,y]/(f,g) is finite dimensional (as its dimension is at least the length of $O_P/(f,g)$). But if we have polynomials $h_1(x)$ and $h_2(y)$ of degrees m and n in (f,g) then k[x,y]/(f,g) has dimension at most that of $k[x,y]/(h_1,h_2)$ which is mn which is finite.
- 5.4b Put P=(0,0) and take any line L not in the tangent cone of Y. We can assume that L is the line y=0, so the terms of lowest degree in f contain x^m (where m is the multiplicity of Y at P). Then $O_P/(f,g) = O_P/(y,x^m+\cdots) = O_Q/(x^m+\cdots)$ which has length m (where O_Q is the local ring of $Q = 0 \in A^1$).
- 5.4c We can assume that L is y=0. If $z\neq 0$, the equation of the curve Y is f(x)+y(*)=0 where f if a polynomial in x of some degree n. Then if x is a root of f of multiplicity m, we have (L.Y)(x,0) = m, so the sums of the intersection multiplicities along the x axis is the number of roots of f which is n. On the other hand, at the point (0:1:0) the intersection multiplicity is d-n as the equation for f is
- locally $z^{d-n} + \cdots + x(*) = 0$. So the sum of all intersection multiplicities is n + d n = d. 5.5 If the characteristic p does not divide d we can use $x^d + y^d + z^d = 0$ Otherwise we can use $xy^{d-1} + z^d = 0$ $yz^{d-1} + zx^{d-1} = 0.$
