

Last time covered 2-manifolds and 2D Dijkgraaf-Witten theory. This lecture covers 3-manifolds and 3D Dijkgraaf-Witten theory.

Here are some examples of 3-manifolds:

Example 1. S^3 is the unit sphere in \mathbb{R}^4 . It is homeomorphic to the one-point compactification of \mathbb{R}^3 . (Compare with S^2 being the one-point compactification of \mathbb{R}^2 .)

Example 2. An oriented Δ -complex structure on S^3 : take two oppositely oriented 3-simplices and glue them together to obtain S^3 . Compare with gluing together two oppositely oriented 2-simplices to get the 2-sphere.

Example 3. Write D^n for the set of points of norm at most 1 in \mathbb{R}^n (D stands for Disk, a la D^2). The boundary operation $X \mapsto \partial X$ satisfies a Leibniz rule. In particular,

$$S^3 = \partial(D^4) \cong \partial(D^2 \times D^2) = (\partial D^2) \times D^2 \cup_{\partial D^2 \times \partial D^2} D^2 \times (\partial D^2)$$

so S^3 can be realized as two solid tori glued together. If you hold a donut in \mathbb{R}^3 , the space outside the donut, plus a point at infinity, forms another donut.

Example 4. More generally than a donut, take a small neighborhood of a graph in \mathbb{R}^3 :

These 3-manifolds are called handlebodies.

Example 5. Remove a knotted string from S^3 :

or

Or remove a small neighborhood of the string

to get a manifold with torus boundary.

Example 6. Let Σ denote a 2-manifold. $S^1 \times \Sigma$ can be described by the quotient

$$(I \times \Sigma)/((0, x) \equiv (1, x)).$$

More generally, for $f : \Sigma \rightarrow \Sigma$ a homeomorphism let

$$M_f = (I \times \Sigma)/((0, x) \equiv (1, f(x))).$$

This is a cylinder over Σ with the two ends glued together in a complicated way.

Example 7. In the previous example, let $\Sigma = T^2 = \mathbb{R}^2/\mathbb{Z}^2$. $\mathrm{SL}_2\mathbb{Z}$ acts on \mathbb{R}^2 by homeomorphisms and sends \mathbb{Z}^2 to itself—so $\mathrm{SL}_2\mathbb{Z}$ acts on T^2 by homeomorphisms. One can let A be any matrix in $\mathrm{SL}_2\mathbb{Z}$ and form the closed 3-manifold M_A .

Example 8. Same as previous example, except let $\Sigma = T^2 \setminus 0$. $\mathrm{SL}_2\mathbb{Z}$ still acts since it preserved 0. It turns out that (2) is homeomorphic to

$$M_{\begin{pmatrix} 0 & -1 \\ 1 & 1 \end{pmatrix}}$$

and (1) is homeomorphic to

$$M_{\begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}}.$$

This is not at all obvious.

Example 9. Here's another even less obvious description of (1). Take two 3-simplices and remove the vertices. (In this situation the vertices are not considered to be ordered.) Glue the two simplices together in the unique way that the following arrows match:

The resulting manifold is homeomorphic to (1).

The construction of 3D Dijkgraaf-Witten theory is completely analogous to the construction of the 2D theory. One significant difference is that the gluing and ungluing maps are not isomorphisms.

Definition 10. 3D Dijkgraaf-Witten theory is the following data. Given (L, x_L) an oriented 2-manifold with Δ -complex structure, let $Z(L, x_L) = \mathbb{C} \mathrm{Hom}(L, G)$. Define the following operations on $Z(L, x_L)$:

- A gluing map given by sticking together G -labelings along oppositely oriented portions of ∂L , e.g.,

$$\text{glue} : Z \left(\begin{array}{c} \text{rectangle with diagonal} \\ \text{top-left: } -, \text{ top-right: } + \\ \text{left: } \uparrow, \text{ right: } \uparrow \\ \text{bottom: } \rightarrow \end{array} \right) \otimes Z \left(\begin{array}{c} \text{triangle} \\ \text{left: } \uparrow, \text{ right: } \uparrow \\ \text{bottom: } \rightarrow \end{array} \right) \rightarrow Z \left(\begin{array}{c} \text{rectangle with diagonal and triangle} \\ \text{top-left: } -, \text{ top-right: } + \\ \text{left: } \uparrow, \text{ right: } \uparrow \\ \text{bottom: } \rightarrow \end{array} \right)$$

$$\begin{array}{c} \begin{array}{c} \text{rectangle with diagonal} \\ \text{top: } h, \text{ bottom: } k \\ \text{left: } g, \text{ right: } k^{-1}gh \\ \text{top-left: } -, \text{ top-right: } + \\ \text{left: } \uparrow, \text{ right: } \uparrow \\ \text{bottom: } \rightarrow \end{array} \otimes \begin{array}{c} \text{triangle} \\ \text{top: } h', \text{ bottom: } g'h' \\ \text{left: } \uparrow, \text{ right: } \uparrow \\ \text{bottom: } \rightarrow \end{array} \mapsto \begin{cases} \begin{array}{c} \text{rectangle with diagonal and triangle} \\ \text{top: } h, \text{ bottom: } k \\ \text{left: } g, \text{ right: } k^{-1}gh \\ \text{top-left: } -, \text{ top-right: } + \\ \text{left: } \uparrow, \text{ right: } \uparrow \\ \text{bottom: } \rightarrow \end{array} & \text{if } g' = k^{-1}gh \\ 0 & \text{otherwise} \end{cases} \end{array}$$

- An ungluing map that splits a G -labeling on a subcomplex of ∂L into two, e.g.,

$$\text{unglue} : Z \left(\begin{array}{c} \text{rectangle with diagonal and triangle} \\ \text{top-left: } -, \text{ top-right: } + \\ \text{left: } \uparrow, \text{ right: } \uparrow \\ \text{bottom: } \rightarrow \end{array} \right) \rightarrow Z \left(\begin{array}{c} \text{rectangle with diagonal} \\ \text{top-left: } -, \text{ top-right: } + \\ \text{left: } \uparrow, \text{ right: } \uparrow \\ \text{bottom: } \rightarrow \end{array} \right) \otimes Z \left(\begin{array}{c} \text{triangle} \\ \text{left: } \uparrow, \text{ right: } \uparrow \\ \text{bottom: } \rightarrow \end{array} \right)$$

$$\begin{array}{c} \begin{array}{c} \text{rectangle with diagonal and triangle} \\ \text{top: } h, \text{ bottom: } k \\ \text{left: } g, \text{ right: } k^{-1}gh \\ \text{top-left: } -, \text{ top-right: } + \\ \text{left: } \uparrow, \text{ right: } \uparrow \\ \text{bottom: } \rightarrow \end{array} \mapsto \begin{array}{c} \begin{array}{c} \text{rectangle with diagonal} \\ \text{top: } h, \text{ bottom: } k \\ \text{left: } g, \text{ right: } k^{-1}gh \\ \text{top-left: } -, \text{ top-right: } + \\ \text{left: } \uparrow, \text{ right: } \uparrow \\ \text{bottom: } \rightarrow \end{array} \otimes \begin{array}{c} \text{triangle} \\ \text{top: } h' \\ \text{left: } \uparrow, \text{ right: } \uparrow \\ \text{bottom: } \rightarrow \end{array} \end{array}$$

- A pairing map between oppositely oriented surfaces

$$Z(L, x_L) \otimes Z(L, -x_L) \rightarrow \mathbb{C}$$

$$\phi \otimes \psi \mapsto \begin{cases} 1 & \phi = \psi \\ 0 & \text{otherwise} \end{cases}.$$

Given (K, x_K) an oriented 3-manifold with Δ -complex structure, define

$$Z(K, x_K) := \frac{1}{|G|^{\#\text{interior vertices}}} \sum_{\phi \in \text{Hom}(K, G)} \partial\phi \in Z(\partial K, \partial x_K).$$

This ends the definition of 3D Dijkgraaf-Witten theory. It is not quite the same definition that Dijkgraaf and Witten originally gave. See the end of this lecture.

Remark 11. As with the 2D theory, for K closed, then

$$Z(K, x_K) = \frac{|\text{Hom}(\pi_1|K|, G)|}{|G|}$$

and so does not depend on the orientation x_K .

Remark 12. The two big theorems about the 2D theory port over to the 3D theory: 1) $Z(K, x_K)$ does not depend on the interior Δ -complex structure, and 2) the Gluing Theorem.

Example 13. Let (K, x_K) be the solid torus with the following oriented Δ -complex structure on the boundary:

Then

$$Z(K, x_K) = \sum_x x \left[\begin{array}{c} e \\ \left[\begin{array}{c} \left[\begin{array}{c} \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ e \end{array} \right]$$

Example 14. Let (K, x_K) be the solid torus with the following oriented Δ -complex structure on the boundary:

Then

$$Z(K, x_K) = \sum_g e \left[\begin{array}{c} g \\ \left[\begin{array}{c} \left[\begin{array}{c} \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ g \end{array} \right]$$

Example 15. Of course $Z(S^3) = \frac{1}{|G|}$ since $\pi_1 S^3$ is the trivial group. Here's another to see it.

Take the two solid tori from the previous two examples. Glue them together respecting the colors. This produces S^3 with one interior vertex. Therefore by the gluing theorem

$$Z(S^3) = \frac{1}{|G|} \left\langle \left(\sum_x x \left[\begin{array}{c} e \\ \left[\begin{array}{c} \left[\begin{array}{c} \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ e \end{array} \right), \left(\sum_g e \left[\begin{array}{c} g \\ \left[\begin{array}{c} \left[\begin{array}{c} \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ g \end{array} \right] \right) \right\rangle = \frac{1}{|G|}$$

(the only term that contributes is the one with $x = g = e$).

Example 16. Think of S^3 as two oppositely oriented 3-simplices glued together. There will be four interior vertices:

$$Z(S^3) = \frac{1}{|G|^4} \left\langle \left(\sum_{g,h,k} g \left[\begin{array}{c} h \\ \left[\begin{array}{c} \left[\begin{array}{c} \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ k \end{array} \right), \left(\sum_{g',h',k'} g' \left[\begin{array}{c} h' \\ \left[\begin{array}{c} \left[\begin{array}{c} \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ \leftarrow \\ \leftarrow \\ \leftarrow \end{array} \right] \\ k' \end{array} \right] \right) \right\rangle = \frac{|G|^3}{|G|^4} = \frac{1}{|G|}$$

(the only terms that contribute are those with $g = g', h = h', k = k'$).

For a complex K recall that K^0 denotes the 0-simplices of K . Then there's a G^{K^0} action on $\text{Hom}(K, G)$ and hence $\mathbb{C} \text{Hom}(K, G)$.

Let (L, x_L) be an oriented surface. Let $x_I x_L$ denote the orientation on $I \times L$. In particular $\partial(x_I x_L)$ is a positive orientation on $\{1\} \times L$ and a negative orientation on $\{0\} \times L$. Inspection of G -labelings shows that

$$Z(I \times L, x_I x_L) = |G|^{|L^0|} \times \text{projection to trivial part of } G^{L^0} \text{ action.}$$

Let (K, x_K) be an oriented 3-manifold, then

$$Z(K, x_K) = \frac{1}{|G|^{\#\text{interior vertices}}} \sum_{\phi \in \text{Hom}(K, G)} \partial \phi$$

is in the trivial part of $G^{(\partial K)^0}$ action, because acting by G^{L^0} permutes the terms in the sum.

Remark 17. Because the invariant for the 3-manifold always sits in the G^{L^0} -trivial part of $Z(L, x_L)$, for a closed surface Σ , Dijkgraaf and Witten define $Z(\Sigma)$ to be the G -trivial part of $\mathbb{C} \text{Hom}(\pi_1 \Sigma, G)$. For M a 3-manifold, $Z(M)$ is defined as above. They also choose put a factor of $\frac{1}{|G|}$ in the pairing map. With these conventions, $Z(I \times \Sigma)$ is assigned the identity map $Z(\Sigma) \rightarrow Z(\Sigma)$ and so their theory gives a functor from the category of 3-cobordisms to the category of vector spaces.

Exercises:

1. Compute $Z(S^1 \times S^2)$.
2. Let X be path connected. Show that $\text{Hom}(\pi_1(X; S), G)/(G^S)$ is in bijection with $\text{Hom}(\pi_1(X, x_0), G)/G$.
3. (a) Let (K, x_K) be a 3-manifold with boundary $(L, x_L) \sqcup (L, -x_L)$. Therefore

$$Z(K, x_K) : Z(L, x_L) \rightarrow Z(L, x_L).$$

Let K' be the result of gluing the two parts of ∂K together. Show that

$$Z(K', x_K) = \frac{1}{|G|^{|L^0|}} \text{tr}(Z(K, x_L)).$$

- (b) Show that $Z(S^1 \times L, x_{S^1} x_L) = |\text{Hom}(\pi_1|L|, G)/G|$.
- (c) Compute $Z(S^1 \times S^2)$ again.

4. Observe that

$$D(G) \cong Z \left(\begin{array}{c} \boxed{\begin{array}{ccc} \rightarrow & & \rightarrow \\ \uparrow & - & \uparrow \\ \rightarrow & & \rightarrow \\ \uparrow & & \uparrow \\ \rightarrow & & \rightarrow \end{array}} \end{array} \right)$$

where the top and bottom edges are identified.

Identify opposite sides of the following to put an oriented Δ -complex structure on T^2 :

Call this Δ -complex structure (T^2, x_{T^2}) .

(a) How does the composition

$$D(G) \xrightarrow{\text{glue}} Z(T^2, x_{T^2}) \xrightarrow{Z(I \times T^2, x_I x_{T^2})} Z(T^2, x_{T^2}) \xrightarrow{\text{unglue}} D(G)$$

behave when restricted to the center of $D(G)$?

(b) Unglue $Z(T^2, x_{T^2})$ in two different ways to provide maps

$$Z(T^2, x_{T^2}) \rightarrow D(G).$$

$$Z(T^2, x_{T^2}) \rightarrow D(G)^*.$$

Show that the first restricts to an isomorphism

$$Z(T^2, x_{T^2})^G \rightarrow \text{center}(D(G)).$$
