# MODULAR FUNCTORIALITY IN THE LOCAL LANGLANDS CORRESPONDENCE 

TONY FENG

#### Abstract

We develop a theory of Smith-Treumann localization and relative parity sheaves in the context of Fargues-Scholze's Geometrization of the Local Langlands Correspondence. We then apply this theory to prove some conjectures of Treumann-Venkatesh concerning mod- $\ell$ Local Langlands functoriality between a reductive group $G$ and its fixed subgroup under an order $\ell$ automorphism. As another application, we calculate the Fargues-Scholze parameters of mod- $\ell$ Howe-unramified toral representations.

## 1. Introduction

1.1. Modular Langlands functoriality. Let $E$ be a local field of residue characteristic $p$ and $G$ be a reductive group over $E$. For simplicity, we assume for now that $G$ is split; beyond the Introduction, the text always treats general $G$. The Local Langlands Correspondence predicts, vaguely speaking, that the smooth representations of $G(E)$ over a field $k$ are controlled by the Langlands dual group $\check{G}$ over $k$.

For example, letting $W_{E} \subset \operatorname{Gal}\left(E^{s} / E\right)$ be the Weil group of $E$, the Local Langlands Correspondence predicts that there should be a natural parametrization of irreducible smooth representations of $G(E)$ over $k$ by " $L$-parameters", which are homomorphisms $W_{E} \rightarrow \check{G}(k)$ up to conjugacy. The existence of such a parametrization has surprising implications for representation theory: for example, a homomorphism $\check{\psi}: \check{H} \rightarrow \check{G}$ of dual groups induces an obvious map

$$
\{L \text {-parameters for } \check{H}\} \xrightarrow{\check{\psi}_{*}}\{L \text {-parameters for } \check{G}\}
$$

and therefore suggests some Langlands functoriality operation from (packets of) irreducible representations of $H(E)$ to (packets of) irreducible representations of $G(E)$. In practice, it is usually difficult to construct such operations directly, or to describe them explicitly in representation-theoretic terms.

In this paper we investigate Langlands functoriality for a specific class of dual homomorphisms $\check{\psi}$ that was identified by Treumann-Venkatesh in TV16. It considers the situation where the reductive group $H$ arises as the fixed points of an order $\ell$ automorphism $\sigma$ of another reductive group $G$, where $\ell$ is a prime different from $p$. Furthermore, we take $k$ to be a field of characteristic $\ell$. In this situation (and under some hypotheses), Treumann-Venkatesh constructed a dual homomorphism $\check{\psi}: \check{H} \rightarrow \check{G}$ over $k$, with a specific property in terms of the Satake isomorphism that we will discuss later. We refer to this situation as modular functoriality, because its construction depends on special features of modular arithmetic (and this paper depends in turn on special features of modular representation theory). By contrast, Langlands' original conjectures were

| Type | $A_{n}$ | $B_{n}, D_{n}$ | $C_{n}$ | $G_{2}, F_{4}, E_{6}$ | $E_{7}$ | $E_{8}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $b(\Phi)$ | 1 | 2 | $n$ | 3 | 19 | 31 |

Figure 1. Excluded primes for each root system.
focused on the case where $k$ has characteristic zero. We note that in many examples the map $\check{\psi}$ does not lift to characteristic zero, and the resulting functoriality is truly specific to modular arithmetic.

The story extends to non-split groups. In that case, the dual group $\check{G}$ should be augmented to the $L$-group ${ }^{L} G \cong \widehat{G} \rtimes W_{E}$, where the action of $W_{E}$ on $\widehat{G}$ reflects the twisting of $G$ over $E$ relative to its split form. This generalization is necessary to treat some of the most interesting examples.

Example 1.1.1. A familiar example is cyclic base change, where $G=\operatorname{Res}_{E^{\prime} / E} H$ for a cyclic $\ell$-extension $E^{\prime} / E$ and $\sigma$ is a generator of $\operatorname{Gal}\left(E^{\prime} / E\right)$ acting on $G$ in the natural way, so that $G^{\sigma}=H$. This particular example lifts to characteristic 0 , but many do not; several examples are tabulated in the ArXiv version of Treumann-Venkatesh's paper [TV14]. We also consider here some interesting examples that are ruled out by the hypotheses of TV14, TV16]: a useful one is where $\sigma$ is conjugation by a strongly regular element of $G$, in which case $H$ is a (not necessarily split!) maximal torus. Note that the work of Treumann-Venkatesh only treats examples where $G$ is simply connected and $H$ is semi-simple.
1.2. Conjectures of Treumann-Venkatesh. We describe some conjectures of Treumann-Venkatesh that will be proved in this paper, up to technical hypothesis that exclude small $\ell$. We again restrict our attention to the case where $G$ and $H$ are split, for simplicity. We let $\mathscr{H}(G, K)$ be the spherical Hecke algebra of $G$ (with respect to some maximal compact subgroup $K$ stable under $\sigma$ ) with coefficients in $k$. Then the Satake isomorphism supplies a $k$-algebra isomorphism

$$
\mathscr{H}(G, K) \cong K_{0}\left(\operatorname{Rep}_{k}(\check{G})\right)
$$

Under some technical assumptions, Treumann-Venkatesh construct a $k$-algebra homomorphism br: $\mathscr{H}(G, K) \rightarrow$ $\mathscr{H}\left(H, K^{\sigma}\right)$ which they call the (normalized) Brauer homomorphism. (The construction uses in an essential way the assumption that char $k=\ell=\operatorname{ord}(\sigma)$.) This implies the existence of a commutative diagram

It is then natural to ask if the dashed map is induced by restriction along a homomorphism $\check{\psi}: \check{H} \rightarrow \check{G}$. If so, then $\check{\psi}$ will be called a " $\sigma$-dual homomorphism". One of the main theorems of Treumann-Venkatesh [TV16, §1.3] is that if $G$ is simply connected and $H$ is semisimple, then a $\sigma$-dual homomorphism exists, with three possible exceptions if $G$ has type $\mathrm{E}_{6}$. In TV14, §1.4(iii)], Treumann-Venkatesh pose the open problem of constructing a $\sigma$-dual homomorphism in full generality. Our first theorem addresses this question.

Theorem 1.2.1. Suppose $\ell>\max \{b(\check{G}), b(\check{H})\}$ where $b(\check{G})$ is the maximum over the bad primes $b(\check{\Phi})$ over all root systems $\check{\Phi}$ of the simple factors of $G$, tabulated in Figure 1, and $b(\check{H})$ is defined similarly. Then a $\sigma$-dual homomorphism $\check{\psi}: \check{H} \rightarrow \check{G}$ exists.

Remark 1.2.2. Theorem 1.2 .1 is not a strict improvement on the work of Treumann-Venkatesh, as our characteristic assumption actually rules out many interesting examples. On the other hand, relaxing the condition that $H$ be semisimple is also interesting in examples; even the case where $H$ is a torus is very useful, as we shall discuss below.

The construction of the $\sigma$-dual homomorphism in TV16] is a tour de force: it invokes classification theorems to tabulate all examples of modular functoriality, and analyzes them case-by-case. By contrast, the proof of Theorem 1.2 .1 is completely uniform across all cases, and makes no use of classification theorems. The idea is quite natural: instead of contemplating the dual groups, we try to categorify the Brauer homomorphism br to a Brauer functor $\widetilde{b r}$ from the Satake category of $G$ to the Satake category of $H$. After equipping this Brauer functor with a Tannakian structure, we obtain the $\sigma$-dual homomorphism for free
from the Geometric Satake equivalence ${ }^{1}$

Although this idea is simple, its implementation is quite involved and will be elaborated upon later; for now we just mention that for the sole purpose of producing the $\sigma$-dual homomorphism, it should be easy to improve the assumption $\ell>\max \{b(\check{G}), b(\check{H})\}$ to " $\ell$ is a good prime for $\check{G}$ and $\check{H}$ ", which for example holds as long as $\ell>5$. The extra inefficiency in our Theorem 1.2 .1 comes from our desire not to work with the usual Geometric Satake equivalence, but with the version on the $\mathrm{B}_{\mathrm{dR}}^{+}$-affine Grassmannians occurring in the work of Fargues-Scholze [FS21], whose geometric representation theory is not as developed.

We next turn to describe conjectures of Treumann-Venkatesh pertaining to the Local Langlands Correspondence. We write $\mathbf{Z}[\sigma]$ for the group ring of $\langle\sigma\rangle \cong \mathbf{Z} / \ell \mathbf{Z}$ and let $N:=1+\sigma+\ldots+\sigma^{\ell-1} \in \mathbf{Z}[\sigma]$. If $\Pi$ is a representation of $G(E) \rtimes \sigma$, then its Tate cohomology groups $\mathrm{T}^{j}(\Pi)$, for $j \in \mathbf{Z} / 2 \mathbf{Z}$, are defined as

$$
\begin{equation*}
\mathrm{T}^{0}(\Pi):=\frac{\operatorname{ker}(1-\sigma \mid \Pi)}{\operatorname{Im}(N \mid \Pi)} \quad \mathrm{T}^{1}(\Pi):=\frac{\operatorname{ker}(N \mid \Pi)}{\operatorname{Im}(1-\sigma \mid \Pi)} \tag{1.1}
\end{equation*}
$$

and the $G(E)$-action on $\Pi$ induces an $H(E)$-action on each $\mathrm{T}^{j}(\Pi)$.
Conjecture 1.2.3 ([TV16, Conjecture 6.3]). Let $\Pi$ be an irreducible smooth representation of $G(E)$ whose isomorphism class is fixed by $\sigma$, so that the $G(E)$-action on $\Pi$ uniquely extends to a $G(E) \rtimes \sigma$-action by [TV16, Proposition 6.1]. Then for each $j \in \mathbf{Z} / 2 \mathbf{Z}$ :
(1) (Admissibility Conjecture) $\mathrm{T}^{j}(\Pi)$ is admissible as a representation of $H(E)$.
(2) (Functoriality Conjecture) The L-parameter of every irreducible $H(E)$-subquotient of $\mathrm{T}^{j}(\Pi)$ is sent by the $\sigma$-dual homomorphism $\check{\psi}$ to the L-parameter for $\Pi^{(\ell)}:=\Pi \otimes_{k, \text { Frob }} \ell$, the Frobenius twist of $\Pi$.

We do not consider Part (1) of Conjecture 1.2 .3 in this paper; it is the subject of current work-inprogress. We will focus on Part (2). At the time of its formulation, the Local Langlands Correspondence was constructed only for certain families of groups, so the precise meaning of Conjecture 1.2 .3 (2) was left vague for general groups. We may now formulate a precise version for all $G$ using the work of Fargues-Scholze [FS21; this is what we will describe next.

Example 1.2.4. For $G=\mathrm{GL}_{n}$, Vignéras had constructed in Vig01 the Local Langlands Correspondence over $k$ (using the characteristic zero version due to Harris-Taylor [HT01]), many years before the work of Fargues-Scholze. This gives a precise meaning to Conjecture $1.2 .3(2)$ when $G$ and $H$ are both general linear groups, and in the context of cyclic base change, special cases have been proven by other authors, as will be discussed more in $\$ 1.6$. Even for this case, our results will depend on the work of Fargues-Scholze.
1.3. The Fargues-Scholze correspondence. An output of the work FS21 of Fargues-Scholze is a map

$$
\left\{\begin{array}{c}
\text { irreducible admissible representations }  \tag{1.2}\\
\pi \text { of } G(E) \text { over } k
\end{array}\right\} / \sim \longrightarrow\left\{\begin{array}{c}
\text { semi-simple } L \text {-parameters } \\
\rho_{\pi}: W_{E} \rightarrow{ }^{L} G(k)
\end{array}\right\} / \sim
$$

that we call the Fargues-Scholze correspondence. We refer to $\rho_{\Pi}$, which is most naturally regarded as an element of $\mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)$, as the Fargues-Scholze parameter of $\Pi$. The map $\Pi \mapsto \rho_{\Pi}$ is expected to be the semi-simplification of "the" hypothetical Local Langlands Correspondence. For specific groups including tori and $\mathrm{GL}_{n}$, the Local Langlands Correspondence has been constructed previously (by class field theory and by Harris-Taylor, respectively), and in these cases it is known that the Fargues-Scholze correspondence is compatible with the previous construction.

[^0]For most groups, the Fargues-Scholze correspondence is quite mysterious. For example it is expected that (1.2) is surjective and has finite fibers, but proving this is wide open. For regular supercuspidal representations of quite general groups, Kaletha [Kal19] has prescribed explicit constructions for the $L$-parameters, which are strongly supported by the expected endoscopic character relations; while for general groups almost nothing is known about the Fargues-Scholze parameters of such representations. We remark that in the cases where the Fargues-Scholze correspondence has been explicated, there have been important geometric implications; an example is the work of Koshikawa Kos21 towards torsion vanishing in the cohomology of Shimura varieties, where the relevant compatibility with the classical LLC is proven in [HKW22].
1.3.1. The functoriality conjecture. We prove the following result concerning modular functoriality in the Fargues-Scholze correspondence, which we take as fulfilling Conjecture 1.2.3(2), away from small $\ell$.

Theorem 1.3.1. Assume $\ell>\max \{b(\check{G}), b(\check{H})\}$. Let $\Pi$ be an irreducible smooth representation of $G(E)$ whose isomorphism class is fixed by $\sigma$. Then for each $j \in \mathbf{Z} / 2 \mathbf{Z}$ and every $H(E)$-irreducible subquotient $\pi$ of $\mathrm{T}^{j}(\Pi)$, the $\sigma$-dual homomorphism $\check{\psi}_{*}: \mathrm{H}^{1}\left(W_{E} ; \widehat{H}(k)\right) \rightarrow \mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)$ sends $\rho_{\pi} \mapsto \rho_{\Pi^{(\ell)}}$.

This result appears as Corollary 9.3 .4 in the main text. It is a consequence of a more powerful statement, Theorem 9.1.1, which treats "derived smooth representations" $\Pi \in D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G(E)\right)$. The derived version is more useful for calculations but less elementary to formulate, so we do not state it here.

Theorem 1.3.1 does not seem to be made any easier by assuming the full categorical conjectures of [FS21], or the conjectural compatibility with Kaletha's explicit Local Langlands Correspondence, or any other standard conjectures about the Local Langlands Correspondence that we know. On the other hand, it may not be unreasonable to speculate that Theorem 1.3.1 could be useful for proving some of these other conjectures. For example, as an application of (the derived version of) Theorem 1.3.1, we calculate explicitly the Fargues-Scholze parameters of certain classes of representations.
1.3.2. Explicit calculation of Fargues-Scholze parameters. The basic idea is that if the $L$-parameter $\rho_{\Pi}: W_{E} \rightarrow$ ${ }^{L} G(k)$ admits some factorization

through an $L$-parameter into ${ }^{L} H(k)$ where $H$ is a torus arising as the fixed points of some appropriate $\sigma$, then Theorem 1.3 .1 identifies $\rho_{\Pi}$ explicitly in terms of the $L$-parameter of $\mathrm{T}^{j}(\Pi)$, which is computable since the Fargues-Scholze correspondence is completely understood for tori. Note that "most" supercuspidal parameters factor through the $L$-group of some (not necessarily split) torus; for example, all of them factor in this way if $p$ is large enough relative to $G$.

We apply this idea to the "Howe-unramified toral supercuspidal representations" considered in work of Chan-Oi [CO. They are generalizations of depth-zero supercuspidals, with an analogous construction but instead using "deeper-level Deligne-Lusztig representations" studied in work of Chan-Ivanov [CI21; consequently, they include supercuspidal representations with arbitrarily high depth. The input for the (modular version of the) Chan-Oi construction is an elliptic unramified torus $T \subset G$ and a character $\theta: T(E) \rightarrow k^{\times}$.

Under the assumption that $\ell>\max \{b(\check{G}), b(\check{H})\}$, and that $T$ contains a strongly regular element of order $\ell$, we prove (Corollary 10.4.2 that some irreducible constituent in the Chan-Oi construction has FarguesScholze parameter of the form

$$
\begin{equation*}
W_{E} \xrightarrow{L_{\theta}}{ }^{L} T(k) \xrightarrow{L_{j}}{ }^{L} G(k), \tag{1.4}
\end{equation*}
$$

where ${ }^{L} j$ is the canonical embedding of the $L$-group of an unramified maximal torus. This is morally in accordance with the prediction with Kaletha's explicit Local Langlands Correspondence for regular supercuspidal representations in Kal19; we say "morally" because Kaletha does not consider modular coefficients. Because the precise definition of a Howe-unramified toral representation is complicated, we defer the precise formulation of our result to Theorem 10.4.1.

We emphasize that the simple appearance of (1.4) belies the intricacy of Kaletha's recipe, which for example involves twisting the most natural (from a representation-theoretic perspective) guess for the $L$ parameter by a subtle "twisting character". In the relatively simple example of epipelagic representations of
unitary groups, these characters were explicated in FRT20 and found to be already very complicated there. The geometric construction of Chan-Oi somehow bakes this twisting character into the geometry (see (CO, $\S 8]$ for more discussion of this point) which is then reflected in our computation.
1.4. Further results. We mention some further results.
1.4.1. Existence of functorial lifts. The following Theorem guarantees the existence of functorial lifts along any $\sigma$-dual homomorphism.

Theorem 1.4.1. Assume $\ell>\max \{b(\check{G}), b(\check{H})\}$. Let $\pi$ be an irreducible smooth representation of $H(E)$ over $k$, with Fargues-Scholze parameter $\rho_{\pi} \in \mathrm{H}^{1}\left(W_{E} ; \widehat{H}(k)\right)$. Then there exists an irreducible smooth representation $\Pi$ of $G(E)$ over $k$ with Fargues-Scholze parameter $\rho_{\Pi} \cong \check{\psi} \circ \rho_{\pi} \in \mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)$.

The more general version (allowing non-split groups) is Theorem 9.5.1. The more general version allows to treat further examples such as the following.

Example 1.4.2 (Base change). Taking $G=\operatorname{Res}_{E^{\prime} / E} H$ for a cyclic $\ell$-extension $E^{\prime} / E$ and $\sigma$ a generator of $\operatorname{Gal}\left(E^{\prime} / E\right)$ acting in the natural way, Theorem 1.4.1 asserts the existence of base change along $E^{\prime} / E$. In equal characteristic and for the Genestier-Lafforgue correspondence, this was established in [Fen, Theorem 1.1].

Example 1.4.3. Take $\sigma$ to be conjugation by a strongly regular $\ell$-torsion element of $G$. Then $H$ is a torus, so every $\rho \in \mathrm{H}^{1}\left(W_{E} ; \widehat{T}(k)\right)$ is realized as a Fargues-Scholze parameter. Then Theorem 1.4.1 implies that every $\rho \in \mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)$ that factors through ${ }^{L} \psi$ is realized as a Fargues-Scholze parameter. It would be interesting to investigate which ${ }^{L} \psi$ can arise, as this might help to show surjectivity of the Fargues-Scholze correspondence over $k$ : recall that if $p$ is not too small relative to $G$, then every supercuspidal $L$-parameter factors through the $L$-group of some torus, and we know that the Fargues-Scholze correspondence is surjective for tori.
1.4.2. Functoriality for the Bernstein center. Let $\mathfrak{Z}(G ; k)$ be the Bernstein center of $G$ with coefficients in $k$, and similarly for $H$. The Fargues-Scholze correspondence $\sqrt{1.2}$ is deduced from the construction of a $k$-algebra homomorphism

$$
\begin{equation*}
\mathrm{FS}_{G}: \operatorname{Exc}_{k}\left(W_{E} ; \widehat{G}\right) \rightarrow \mathfrak{Z}(G ; k) \tag{1.5}
\end{equation*}
$$

where $\operatorname{Exc}_{k}\left(W_{E} ; \widehat{G}\right)$ is the excursion algebra (over $k$ ).
Building on ideas of Treumann-Venkatesh, we construct a map of Bernstein centers

$$
\begin{equation*}
\mathfrak{Z}_{\mathrm{TV}}: \mathfrak{Z}(G ; k) \rightarrow \mathfrak{Z}(H ; k) \tag{1.6}
\end{equation*}
$$

which we call the Treumann-Venkatesh homomorphism. We show in Theorem 9.3 .2 that if $\ell>\max \{b(\check{G}), b(\check{H})\}$, then there is a commutative diagram

This shows that $\mathfrak{Z}_{\mathrm{TV}}$ realizes functoriality for the Bernstein center. In fact, it is the main ingredient to the proof of Theorem 1.4.1.
1.5. Methods. The proofs of the aforementioned results synthesize recent breakthroughs in several different areas of mathematics, including:
(1) The work TV16, Tre19 of Treumann-Venkatesh on Smith theory and Langlands functoriality.
(2) The work JMW14, JMW16 of Juteau-Mautner-Williamson on parity sheaves in modular representation theory.
(3) The work [FS21] of Fargues-Scholze on the geometrization of the Local Langlands Correspondence.

Let sketch vaguely how these ingredients fit together. In the sketch below, we use some abbreviated and simplified notation which does not match that of the main body of the text. We begin by commenting on the proof of Theorem 1.2.1. As explained earlier, the proof is based on categorifying the Brauer homomorphism of Treumann-Venkatesh to a Brauer functor, from perverse sheaves on the affine Grassmannian $\mathrm{Gr}_{G}$ for $G$ to
perverse sheaves on the affine Grassmannian $\mathrm{Gr}_{H}$ for $H$, which should be Tannakian (additive, symmetric monoidal, and compatible with the fiber functor).

The construction of the Brauer homomorphism is based on the observation that the restriction of $\sigma$ equivariant functions from $G(E) / K$ to $H(E) / K^{\sigma}$ has the miraculous property of being compatible with convolution specifically in characteristic $\ell$ (the order of $\sigma$ ). The naive categorification of this operation would be restriction of sheaves from $\mathrm{Gr}_{G}$ to $\mathrm{Gr}_{H}$, but the miracle does not (naively) persist to the level of sheaves. Instead we apply an operation that we call Smith-Treumann localization, which is restriction followed by a certain Verdier quotient. The Smith-Treumann localization functor is then monoidal to some extent, but does not interact well with perversity. However it turns out that it can be made to interact well with parity sheaves in the sense of Juteau-Mautner-Williamson. This allows to lift Smith-Treumann localization to a functor from perverse parity sheaves on $\mathrm{Gr}_{G}$ to perverse parity sheaves on $\mathrm{Gr}_{H}$. Then studying the interaction of parity and perversity on affine Grassmannians allows to extend the functor to all perverse sheaves (under conditions on $\ell$ ).

The preceding construction could have been executed on the "classical" affine Grassmannian as soon as $\ell$ is good for $\check{G}$ and $\check{H}{ }^{2}$ However, at the next step we want to combine it with the constructions of FarguesScholze, so we actually need carry everything out on the $\mathrm{B}_{\mathrm{dR}}^{+}$-affine Grassmannians and their BeilinsonDrinfeld variants, which are built out of the period rings of $p$-adic Hodge theory. As those objects live in the world of $p$-adic geometry, which behaves very differently from algebraic geometry in several key aspects (for example, there is no good theory of constructible sheaves), there are substantial technical difficulties to overcome in order to develop the appropriate technology in this new setting. We defer discussion of these technical difficulties to the individual sections in which they appear. The formalism that we develop here lays the groundwork for further applications of geometric representation theory to $p$-adic geometry, which we hope to pursue in future work.

Figure 2. This cartoon (produced with the aid of ChatGPT after much coaxing) depicts the Brauer functor $\tilde{b r}$ interfacing with the Tate cohomology of moduli of local shtukas and with the $\sigma$-dual homomorphism $\check{\psi}$.

Next we turn towards the proof of Theorem 1.3.1. For this we need to integrate the Brauer functor with the construction of the Fargues-Scholze correspondence for $G$ and for $H$. The Fargues-Scholze correspondence for $G$ can be obtained by constructing excursion operators on the cohomology of moduli spaces Sht $_{G}$ of local $G$-shtukas with coefficients in Satake sheaves coming from $\mathrm{Gr}_{G}$. We need to compare such cohomology groups to the ones obtained from applying the Brauer functor to get Satake sheaves on $\mathrm{Gr}_{H}$, transporting them to the moduli spaces $\mathrm{Sht}_{H}$ of local $H$-shtukas, and then taking cohomology. This comparison is mediated by equivariant localization for Tate cohomology. Figure 2 depicts a cartoon of the strategy. From this

[^1]comparison we extract relations among certain excursion operators for $\check{G}$ and for $\check{H}$, which are ultimately used to establish Theorem 1.3.1.

### 1.6. Related work. We note some related work on the problems studied here.

1.6.1. The functoriality conjecture. We focus first on the "functoriality conjecture", Conjecture 1.2.3(2). Ronchetti Ron16 studied Conjecture 1.2 .3 (2) in the special case of cyclic base change for $\mathrm{GL}_{n}$, proving it for depth-zero cuspidal representations "of level zero and minimal-maximal type".

Dhar-Nadimpalli [DN23] studied Conjecture 1.2 .3 (2) in the special case of cyclic base change for $\mathrm{GL}_{n}$, proving it for generic representations (i.e., those possessing mod- $\ell$ Whittaker models).

The earlier work of the author [Fen] proved the analogous statement to Theorem 1.3.1 for the GenestierLafforgue correspondence (in equal characteristic) in the special case of cyclic base change, and in doing so introduced a primordial form of some ideas developed here. We point out several differences.

- The methods of [Fen were based on local-global compatibility, and were thus fundamentally restricted to the function field setting. Here our methods are purely local, and we encompass both mixed characteristic and equal characteristic local fields. To do this, we work in the context of $p$-adic geometry, which presents substantial new difficulties.
- The argument of [Fen was restricted to the case of cyclic base change, for both local and global reasons. On the local side, the $\sigma$-dual homomorphism is obvious for cyclic base change, and the construction of the Brauer functor in that case exploited some simplifying special features of cyclic base change; the present paper debuts more general and conceptual arguments to treat the local aspects in arbitrary generality (as long as $\ell$ is not too small). We still do not know how to generalize the global arguments even in the function field case, but fortunately they are irrelevant for the new approach.
The author's work $\left.\mathrm{BFH}^{+}\right]$with Böckle-Harris-Khare-Thorne explicates Conjecture 1.2 .3 (2) for the GenestierLafforgue correspondence in the special case of cyclic base change for toral supercuspidals, assuming several conjectures about torsion in the cohomology of deep-level Deligne-Lusztig varieties. The analogous results for the Fargues-Scholze correspondence are subsumed by the $L$-parameter calculations in $\$ 10$.
1.6.2. The $\sigma$-dual homomorphism. The work RW22 of Riche-Williamson, which gives a geometric proof of the linkage principle, is not logically related to problems we study here, but has some philosophical similarities. We apply Smith-Treumann localization from $\mathrm{Gr}_{G}$ to $\mathrm{Gr}_{H}$ coming from an automorphism of $G$, while Riche-Williamson apply (a slightly different form of) Smith-Treumann localization to a self-embedding of $\mathrm{Gr}_{G}$ coming from the action of $\mu_{\ell} \subset \mathbf{G}_{m}$ via loop rotation.

The paper [LL21] of Leslie-Lonergan also applies Smith-Treumann localization along this self-embedding, in attempt to give a geometric construction of the Frobenius contraction functor on $\operatorname{Rep}_{k}(\breve{G})$. The formalism of localization that they develop is more similar to the one that we use in this paper.
1.7. Organization of the paper. We now indicate the structure of the paper.

In $\$ 2$ we collect some notation and abbreviations used commonly throughout the paper.
In 3 we develop a general formalism of Smith-Treumann localization for diamonds, which refers to a certain type of sheaf restriction operation from a diamond $Y$ to its $\sigma$-fixed points. Then in $\$ 4$ we calculate the $\sigma$-fixed points of various diamonds associated to $G$, such as the $\mathrm{B}_{\mathrm{dR}}^{+}$-affine Grassmannian and its BeilinsonDrinfeld or twisted variants, as well as moduli spaces of local $G$-shtukas. These calculations are used when applying Smith-Treumann localization to such spaces.

In $\$ 5$, we develop a notion of "relative parity sheaves" on the Beilinson-Drinfeld affine Grassmannians arising in $p$-adic geometry. Then in $\$ 6$ we prove that away from small characteristics, (normalized) relative parity sheaves are relative perverse and correspond under the Geometric Satake equivalence to tilting modules; this is analogous to a theorem of Juteau-Mautner-Williamson from [JMW16. In fact, each of 83 , $\$ 5$, and $\$ 6$ is parallel to some existing theory in algebraic geometry, but there are non-trivial new issues encountered in the setting of $p$-adic geometry, which we try to illuminate at the beginnings of the respective sections.

In $\S 7$, we construct the Brauer functor and establish its properties, proving Theorem 1.2.1. Then in $\S 8$ we study the (Tate) cohomology of moduli stacks of shtukas, and integrate it with the Brauer functor in order to prove certain identities of excursion operators. The applications ripen for picking in $\$ 9$ where we
combine the preceding sections to prove Theorem 1.3.1. Theorem 1.4.1. construct the Treumann-Venkatesh homomorphism and establish the commutative diagram 1.7.

Finally, in $\S 10$ we study the example where $\sigma$ is conjugation by a strongly regular order- $\ell$ element of an unramified elliptic maximal torus of $G$. We calculate the $\sigma$-dual embedding, the Tate cohomology of deep level Deligne-Lusztig varieties and their compact inductions, and deduce explicit computations of FarguesScholze parameters.

The beginnings of individual sections summarize their contents in more detail.
1.8. Acknowledgments. It is a pleasure to acknowledge Brian Conrad, Olivier Dudas, Ian Gleason, Jesper Grodal, David Hansen, Tasho Kaletha, Teruhisa Koshikawa, Gopal Prasad, Simon Riche, Peter Scholze, Sug Woo Shin, Jay Taylor, David Treumann, Akshay Venkatesh, and Geordie Williamson for relevant discussions. Special thanks to Venkatesh for posing the question of finding a uniform construction of the $\sigma$-dual homomorphism to me in 2017, to Scholze for the proof of Lemma 3.1.5, and to Conrad for help with Lemma 4.2.1. Thanks also to Johannes Anschütz, Shachar Carmeli, Jessica Fintzen, and Mingjia Zhang for comments on a draft. Parts of this paper were completed at the Hausdorff Institute for Mathematics, funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) under Germany's Excellence Strategy - EXC-2047/1-390685813. This work was supported by NSF Postdoctoral Fellowship DMS-1902927 and NSF Grant DMS-2302520.

## 2. Notation

We fix a prime $p$.
2.1. Local fields. We let $E$ be a local field of residue characteristic $p, \mathcal{O}_{E}$ its ring of integers, $\varpi_{E}$ a uniformizer, and $\mathbf{F}_{q}=\mathcal{O}_{E} / \varpi_{E}$ its residue field.

Let $\breve{E}$ be the completion of the maximal unramified extension of $E$. For a reductive group $G / E, B(G)$ denotes the Kottwitz set of $G$, i.e., elements of $G(\breve{E})$ modulo Frobenius-conjugacy.

Let $E^{s}$ be a separable closure of $E$ and $W_{E} \subset \operatorname{Gal}\left(E^{s} / E\right)$ be the Weil group of $E$.
2.2. The group $\Sigma$. Throughout $\ell$ denotes a prime number and $\Sigma$ denotes a finite cyclic group of order $\ell$. The notation $\sigma$ always denotes a generator of $\Sigma$; conversely, if an automorphism $\sigma$ is constructed first then $\Sigma$ always denotes the group generated by $\sigma$. Some constructions (e.g., Tate cohomology) are phrased in terms of $\sigma$, but ultimately all constructions are independent of the choice of $\sigma$.

We denote by $N$ the element $1+\sigma+\ldots+\sigma^{\ell-1} \in \mathbf{Z}[\Sigma]$.
For an object $Y$ with an action of $\Sigma$, we denote by $Y^{\sigma}$ or $\operatorname{Fix}(\sigma, Y)$ the $\sigma$-fixed points of $Y$.
2.3. Reductive groups. Throughout $G$ denotes a reductive group over $E$. When the notation $H$ appears, it refers to a reductive group arising as the subgroup of $G$ fixed by an action of $\Sigma$. We denote by $\iota: H \rightarrow G$ the tautological embedding, and we use the same notation for induced maps such as $H(E) \rightarrow G(E), B(H) \rightarrow$ $B(G), \mathrm{Gr}_{H} \rightarrow \mathrm{Gr}_{G}$, etc.

For a torus $T$, we denote by $X_{*}(T)$ and $X^{*}(T)$ the cocharacter and character groups of $T$, respectively, and by $X_{*}(T)^{+}$and $X^{*}(T)^{+}$the subsets of dominant (co)characters.

We denote by $\operatorname{Rep}_{k}^{\mathrm{sm}} G(E)$ the category of smooth representations of $G(E)$ over $k$.
2.4. Perfectoid spaces. The notation $\left(C, C^{+}\right)$will always mean that $C$ is an algebraically closed perfectoid field and $C^{+} \subset C$ is an open bounded valuation subring.

Following [FS21], we denote by Perf $=\operatorname{Perf}_{\overline{\mathbf{F}}_{p}}$ the category of perfectoid spaces over $\overline{\mathbf{F}}_{p}$.
2.5. Coefficients. Throughout $k$ denotes an algebraically closed field of characteristic $\ell=\# \Sigma$, where $\ell$ is a prime number different from $p$. We denote by $\mathbb{O}:=W(k)$ the Witt vectors of $k$.

We write Frob: $k \rightarrow k$ for the absolute Frobenius automorphism $x \mapsto x^{\ell}$.
2.6. Sheaves. We will use $\Lambda$ to denote a coefficient ring finite over $\mathbb{O}$. In particular, $\Lambda$ is $\ell$-adically complete. The six-functor formalism for such sheaves is developed in Sch22 (the adic case is in §27 of loc. cit.).
Definition 2.6.1. We say that a map $f: Y \rightarrow Y^{\prime}$ of small v-stacks on Perf is shriekable if it is compactifiable, representable in locally spatial diamonds, and has locally finite dim. trg. This is exactly the hypothesis in Sch22, §1] for $R f_{!}: D_{\text {ét }}(Y ; \Lambda) \rightarrow D_{\text {ét }}\left(Y^{\prime} ; \Lambda\right)$ to exist, and under the same assumptions its right adjoint $R f^{!}: D_{\text {ét }}\left(Y^{\prime} ; \Lambda\right) \rightarrow D_{\text {ét }}(Y ; \Lambda)$ exists.

For a shriekable map $f: Y \rightarrow Y^{\prime}$, we denote by $\mathbb{D}_{Y / Y^{\prime}}$ the relative Verdier duality functor,

$$
\mathbb{D}_{Y / Y^{\prime}}(-):=\mathcal{R} \mathcal{H o m} D_{D_{\mathrm{et}}(Y ; \Lambda)}\left(-, f^{!} \Lambda\right)
$$

We abuse notation and write $\mathbb{D}_{Y / Y^{\prime}}:=\mathbb{D}_{Y / Y^{\prime}}(\Lambda)=f^{!} \Lambda$ for the relative dualizing sheaf. We omit $Y^{\prime}$ from the notation in the case $Y^{\prime}=\operatorname{Spd} \overline{\mathbf{F}}_{p}$.
2.7. Categories. For a category $C$ with an action of a group $\Gamma$, we let $C^{B \Gamma}$ denote the category of $\Gamma$ equivariant objects in $C$. This comes equipped with a forgetful functor to $C$. If $C$ is a triangulated category with a natural stable $\infty$-categorical enhancement, then by $C^{B \Gamma}$ we mean the homotopy category of the $\Gamma$-equivariant objects in its stable $\infty$-categorical enhancement.

For an $A$-linear abelian category C and a commutative ring homomorphism $A \rightarrow B$, we abbreviate

$$
\mathrm{C} \otimes_{A} B:=\mathrm{C} \otimes_{A-\mathrm{Mod}}(B-\mathrm{Mod})
$$

When $A=\mathbb{O}$ and $B=k$, we write

$$
\mathbb{F}: \mathrm{C} \rightarrow \mathrm{C} \otimes_{\mathbb{O}} k
$$

for the tautological base change.

## 3. Smith-Treumann localization for diamonds

In this section we develop for diamonds a form of Smith-Treumann localization, which refers to a type of sheaf-theoretic equivariant localization from a $\Sigma$-equivariant space to its $\Sigma$-fixed points. There is a loose analogy between Smith-Treumann localization and the perhaps more familiar hyperbolic localization for spaces with a $\mathbf{G}_{m}$-action.

The output of the theory looks similar to that for complex algebraic varieties or schemes (developed in Tre19] and RW22]). However, the details of the proofs are quite different, owing to the different behavior of étale sheaves on adic spaces. For example, the theory relies crucially on finiteness results, which in the case of schemes comes from quasi-compactness (among other things). On the other hand, non-quasicompactness is ubiquitous in $p$-adic geometry. For example, the complement of a closed subspace is usually not quasicompact, hence the extension-by-zero from such a complement is not constructible; this example already illustrates that we will frequently need to contend with non-constructible sheaves.

The contents of this section are as follows. In $\$ 3.1$ we codify the notion of "extra small" v-stacks. The adjective "extra small" is a slight strengthening of "small", and guarantees that we can approximate the vstack by quasicompact subspaces. In $\$ 3.2$, we define the (large) "Tate category" of a locally spatial diamond, following ideas of Treumann [Tre19] but with modifications as in [Fen, §3] to allow infinite dimensional sheaves. In $\$ 3.4$ we prove technical bounds for the tor-dimension of various sheaf operations, in order to show in that these operations pass to the Tate category, which we do in 83.5 . In 8.6 we define the "Smith operation", a kind of localization functor to the $\Sigma$-fixed points, and establish compatibility properties that may be thought of as forms of equivariant localization. Finally, in $\$ 3.7$ we define Tate cohomology and various generalizations of it.
3.1. Extra small v-stacks. Let $\omega_{1}$ be the first uncountable cardinal. Recall that an $\omega_{1}$-cofiltered inverse system $I$ is one for which any functor $J \rightarrow I$, with $J$ a countable category, extends to $J^{\triangleleft} \rightarrow I$, where the cone $J^{\triangleleft}$ consists of $J$ plus an extra object with a unique map to each object of $J$.

Definition 3.1.1 (Extra small v-stacks). We say that a v-stack $Y$ is extra small if for any $\omega_{1}$-cofiltered inverse system $\left\{S_{i}=\operatorname{Spa}\left(R_{i}, R_{i}^{+}\right)\right\}_{i \in I}$ of affinoid perfectoid spaces with inverse limit $S=\operatorname{Spa}\left(R, R^{+}\right)$, the natural map

$$
Y(S) \rightarrow \underset{i \in I}{\lim } Y\left(S_{i}\right)
$$

is an isomorphism.

The following Lemma justifies the terminology.
Lemma 3.1.2. If a v-stack $Y$ is extra small, then $Y$ is small.
Proof. The proof is contained in the first paragraph of [FS21, Proof of Proposition III.1.3].
Remark 3.1.3. Informally speaking, all the small v-stacks that have come up in our experience are also extra small. The remark below [FS21, Proposition III.1.3] suggests that all "reasonable" v-stacks are extra small.

Example 3.1.4. The last paragraph of the proof of [FS21, Proposition III.1.3] shows that Bun ${ }_{G}$ is extra small. By minor variations on this argument, the following v-stacks are also extra small.
(1) The local Hecke stack $\mathcal{H} \mathrm{ck}_{G /\left(\operatorname{Div}_{X}^{1}\right)^{I}}$ [FS21, Definition VI.1.6], and the global Hecke stack $\operatorname{Hck}_{G}^{I}$ [FS21, §IX.2].
(2) The Beilinson-Drinfeld Grassmannian $\operatorname{Gr}_{G,\left(\operatorname{Div}_{X}^{1}\right)^{I}}$ [FS21, Definition VI.I.8].
(3) The moduli spaces of local shtukas $\operatorname{Sht}_{\left(G, b, \mu_{\bullet}\right), K}$ SW20, Lecture 23].

The importance of extra smallness (for us) is to control the cohomological dimension of direct image along open embeddings. For quasi-compact open embeddings, the direct image is actually exact, but we will typically be contending with non-quasicompact open embeddings. Under hypotheses that spaces are extra small, we will be able to approximate open embeddings by quasicompact ones, as articulated in the following Lemma (pointed out by Peter Scholze).

Lemma 3.1.5. Let $Y$ be a locally spatial diamond admitting a countable open cover by spatial diamonds $Y_{n}$. Let $Z \hookrightarrow Y$ be a closed embedding such that $Z \cap Y_{n}$ is extra small for each $n$. Then $U:=Y \backslash Z$ is a countable union of quasicompact open subspaces.

Proof. If $Y_{n} \backslash Z_{n}$ is a countable union of quasicompact open subsets for each $n$, then

$$
Y \backslash Z=\bigcup_{n}\left(Y_{n} \backslash Z_{n}\right)
$$

is also a countable union of quasicompact open subsets. Therefore, renaming $Y_{n}$ to $Y$ and $Z_{n}$ to $Z$, we may assume that $Y$ is spatial and $Z$ is extra small, with the goal of showing that $U:=Y \backslash Z$ is a countable union of quasicompact open subsets.

Consider the collection $\mathcal{Z}$ of closed sub-diamonds $Z_{i} \subset Y$ such that $Z_{i}$ contains $Z$ and $Y \backslash Z_{i}$ is a countable union of quasi-compact open subsets. Viewing $\mathcal{Z}$ as a partially ordered set under inclusion, we claim that $\mathcal{Z}$ is $\omega_{1}$-cofiltered. Indeed, if $I$ is countable then we have

$$
Y \backslash \bigcap_{i \in I} Z_{i}=\bigcup_{i \in I}\left(Y \backslash Z_{i}\right)
$$

is a countable union of countable unions of quasi-compact open subsets, so $\bigcap_{i \in I} Z_{i} \in \mathcal{Z}$.
There is an obvious map

$$
\begin{equation*}
Z \rightarrow \lim _{Z_{i} \in \mathcal{Z}} Z_{i} \tag{3.1}
\end{equation*}
$$

which we claim is an isomorphism. Recall that closed sub-diamonds of $Y$ are determined by their underlying topological spaces, as follows from [Sch22, Proposition 11.20] (the generalization of this statement to v-stacks is AGLR22, Proposition 1.3]), so it suffices to check (3.1) at the level of topological spaces. Any point of the open subspace $|Y \backslash Z|$ lies in a quasicompact open subset since $Y$ is spatial. This shows the second equality in the sequence of identifications

$$
\left|\lim _{Z_{i} \in \mathcal{Z}} Z_{i}\right|=\lim _{Z_{i} \in \mathcal{Z}}\left|Z_{i}\right|=|Z|,
$$

verifying the claim.
Since $Y$ is spatial, there exists [Sch22, Proposition 11.24] a quasi-pro-étale cover of $Y$ by a strictly totally disconnected space, which is of the form $\operatorname{Spa}\left(B, B^{+}\right) \rightarrow Y$ by [Sch22, Proposition 1.15]. Recall that a closed subspace of a strictly totally disconnected space is again strictly totally disconnected by Sch22, Proposition 7.16], and then affinoid by [Sch22, Lemma 7.5]. Hence for each $Z_{i} \in \mathcal{Z}$, the cover pulls back to
a cover $\operatorname{Spa}\left(A_{i}, A_{i}^{+}\right) \rightarrow Z_{i}$ where $\operatorname{Spa}\left(A_{i}, A_{i}^{+}\right)$is strictly totally disconnected. We showed that the system $\left\{\operatorname{Spa}\left(A_{i}, A_{i}^{+}\right)\right\}_{Z_{i} \in \mathcal{Z}}$ is $\omega_{1}$-cofiltered. Then, letting $\left.\operatorname{Spa}\left(A, A^{+}\right):=\lim _{Z_{i} \in \mathcal{Z}} \operatorname{Spa}\left(A_{i}, A_{i}^{+}\right)\right\}^{3}$ the composite map

$$
\operatorname{Spa}\left(A, A^{+}\right)=\lim _{Z_{i} \in \mathcal{Z}} \operatorname{Spa}\left(A_{i}, A_{i}^{+}\right) \rightarrow{\underset{Z_{i} \in \mathcal{Z}}{ }}_{\lim _{i}} Z_{i}=Z
$$

factors through some $\operatorname{Spa}\left(A_{i}, A_{i}^{+}\right) \rightarrow Z$ since $Z$ is extra small. This gives a retract $Z_{i} \rightarrow Z$ over $Y$, which must then be an isomorphism since these are closed subdiamonds of $Y$. Hence $Z \in \mathcal{Z}$, which means by definition that $Y \backslash Z$ is a countable union of quasi-compact open subsets.

Motivated by Lemma 3.1.5, we make the following definition.
Definition 3.1.6. We say that a locally spatial diamond $Y$ is ( $\omega_{0}-$ )locally spatial if $Y$ can be written as a (countable) union $\bigcup_{n} Y_{n}$ of open spatial sub-diamonds. (Recall that $\omega_{0}=\aleph_{0}$ is the cardinality of the natural numbers.) We say that a closed subdiamond $Z \hookrightarrow Y$ is $\omega_{0}$-locally extra small if such a union can be arranged so that $Y_{n} \cap Z$ is extra small for each $n$.

We say that a morphism of v-stacks $f: Y^{\prime} \rightarrow Y$ is $\left(\omega_{0^{-}}\right)$locally spatial if for any spatial diamond $X$ and any map $X \rightarrow Y$, the fibered product $X \times_{Y} Y^{\prime}$ is ( $\omega_{0}$ )locally spatial.

Example 3.1.7. Let $i: Z \hookrightarrow Y$ be a closed embedding of $\omega_{0}$-locally spatial diamonds. If $Z \subset Y$ is $\omega_{0}$-locally extra small, then Lemma 3.1.5 says that the complementary open embedding $j: U \hookrightarrow Y$ is $\omega_{0}$-locally spatial.

Definition 3.1.8. We say that a locally spatial diamond $Y$ has $\ell$-cohomological dimension $\leq d$ if its co-
 dimension $\leq d$ for some $d<\infty$.

Example 3.1.9. The following statements are used to bound the $\ell$-cohomological dimension in practice. Recall from Sch22, Definition 21.1] that the dimension of a locally spectral space is the supremum of the lengths of chains of specializations. By [Sch22, Proposition 21.11], if $Y$ is a spatial diamond of finite dimension, then

$$
Y \text { has } \ell \text {-cohomological dimension } \leq \operatorname{dim} Y+\sup _{y} \operatorname{cd}_{\ell} y
$$

where $y$ runs through maximal points of $Y$. According to Sch22, Proposition 21.16], if $f: Y \rightarrow \operatorname{Spa}\left(C, C^{+}\right)$ is a map of locally spatial diamonds, then $\operatorname{cd}_{\ell} y \leq \operatorname{dim} . \operatorname{trg} f$ for all maximal points $y \in Y$.

Lemma 3.1.10. Let $A$ be a noetherian ring. Let $Y$ be an $\omega_{0}$-locally spatial diamond with $\ell$-cohomological dimension $\leq d$. Let $Z \hookrightarrow Y$ be an $\omega_{0}$-locally extra small closed subdiamond with (open) complement $j: U \hookrightarrow$ $Y$. Then $\mathrm{R} j_{*}: D_{e ́ t}(U ; A) \rightarrow D_{e t t}(Y ; A)$ has cohomological dimension $\leq d+1$.
Proof. The statement is local, so we may immediately reduce to the case that $Y$ is a spatial diamond and $Z \hookrightarrow Y$ is extra small.

By Lemma 3.1.5, there is a countable sequence of quasicompact open embeddings $j_{n}: U_{n} \hookrightarrow Y$ such that $U_{n} \subset U$ and $\lim _{\rightarrow n} U_{n}=U$. Hence we have

$$
\mathrm{R} j_{*} \cong \underset{n}{\mathrm{R}}{\underset{\mathrm{lim}}{n}}^{\mathrm{R}} j_{n *} j_{n}^{*}: D_{\text {ét }}(U ; A) \rightarrow D_{\text {ét }}(Y ; A) .
$$

By Sch22, Lemma 21.13], the (derived) direct image along a quasi-compact open embedding is exact, hence has cohomological dimension zero. This applies to $j_{n}$ for every $n$. Therefore, it suffices to see that the derived inverse limit functor $\mathrm{Rlim}_{n}$, along a countable index set, has finite cohomological dimension. Thanks to this countability, Rlim ${ }_{n} A_{n}$ can be expressed as

$$
\begin{equation*}
\underset{n}{\mathrm{Rlim}} A_{n} \cong \operatorname{cone}\left(\mathrm{R} \prod_{n} A_{n} \rightarrow \mathrm{R} \prod_{n} A_{n}\right)[-1] \tag{3.2}
\end{equation*}
$$

where $\mathrm{R} \prod_{n}$ is the derived functor of the product, defined as the product of injective resolutions of the terms. By the standard generalities, $\mathrm{R} \prod_{n}$ can be calculated using a product of acyclic (for the global sections functor) resolutions, which can be taken to be of length bounded by the cohomological dimension of $Y$,

[^2]which by assumption is $d<\infty$. Then from $\sqrt[3.2]{ }$ we see that ${\underset{\gtrless}{\gtrless}}_{n}$ has cohomological dimension at most $d+1$.

Corollary 3.1.11. In the situation of Lemma 3.1.10. if $\mathcal{K} \in D_{\text {ét }}^{b}(U ; A)$ has finite tor-dimension then $\mathrm{R} j_{*} \mathcal{K} \in$ $D_{\text {ét }}(Y ; A)$ has finite tor-dimension.

Proof. This is a special case of [SGA73, Exposé XVII, Théorème 5.2.11], which applies because R $j_{*}$ has finite cohomological dimension by Lemma 3.1.10 and the fact [Sch22, Proposition 14.3] that $Y_{\text {ét }}$ has enough points, thanks to $Y$ being locally spatial.
3.2. The Tate category. Let $\Lambda$ be a finite commutative $W(k)$-algebra; we will be most interested in the cases $\Lambda=k$ or $W(k)$. Recall that $\Sigma$ is a cyclic group of order $\ell$ and $\Lambda[\Sigma]$ denotes its group ring.
Definition 3.2.1. Let $Y$ be a small v-stack. We define $\operatorname{Flat}^{b}(Y ; \Lambda[\Sigma]) \subset D_{\text {ett }}^{b}(Y ; \Lambda[\Sigma])$ to be the full subcategory consisting of complexes with finite tor-dimension Sta20, Tag 0651], i.e., which have tor-amplitude in $[a, b]$ for some $a, b \in \mathbf{Z}$.
Definition 3.2.2. We define the (large) Tate category of $Y$ (with respect to $\Lambda$ ) to be the Verdier quotient category

$$
\operatorname{Shv}\left(Y ; \mathcal{T}_{\Lambda}\right):=D_{\text {êt }}^{b}(Y ; \Lambda[\Sigma]) / \operatorname{Flat}^{b}(Y ; \Lambda[\Sigma])
$$

(A "small" variant of the Tate category will appear later in $\$ 5.2$.) We denote the tautological projection map from $D_{\text {ett }}^{b}(Y ; \Lambda[\Sigma])$ to $\operatorname{Shv}\left(Y ; \mathcal{T}_{\Lambda}\right)$ by

$$
\mathbb{T}^{*}: D_{\text {êt }}^{b}(Y ; \Lambda[\Sigma]) \rightarrow \operatorname{Shv}\left(Y ; \mathcal{T}_{\Lambda}\right)
$$

Remark 3.2.3. We will only be using the large Tate category for $\Lambda=k$, but some arguments are repeated in the small version which also gets used for $\Lambda=W(k)$, so we formulate it in more generality.

For $\Lambda=k$, the following Lemma (pointed out by Jesper Grodal) gives an alternative characterization of the subcategory $\operatorname{Flat}^{b}(Y ; k[\Sigma])$, showing that it is determined by conditions on geometric stalks.

Lemma 3.2.4. The subcategory Flat $^{b}(Y ; k[\Sigma]) \subset D_{e t t}^{b}(Y ; k[\Sigma])$ coincides with the full subcategory spanned by objects whose stalks at all geometric points have finite tor-dimension over $k[\Sigma]$.
Proof. We apply [Sta20, Tag 0DJJ] which immediately gives one containment: if $\mathcal{K} \in D_{\text {êt }}^{b}(Y ; k[\Sigma])$ has finite tor-dimension over $k[\Sigma]$, then all its stalks at geometric points have finite tor-dimension over $k[\Sigma]$.

For the other containment, again by [Sta20, Tag 0DJJ] it suffices to show that if all the geometric stalks of $\mathcal{K} \in D_{\text {ett }}^{b}(Y ; k[\Sigma])$ have finite tor-amplitude, then there is a uniform bound on the tor-amplitude of the stalks. Indeed, since $\mathcal{K}$ is bounded we may pick a bounded complex representing it, say concentrated in degrees $[a, b]$. It then suffices to show: if $K$ is a complex of $k[\Sigma]$-modules concentrated in degrees $[a, b]$ and has finite tor-dimension, then in fact its tor-amplitude lies in $[a, b]$.

Since $k[\Sigma]$ is Artinian, the properties of being flat and projective over $k[\Sigma]$ coincide by [Sta20, Tag 051E]. Therefore $\mathcal{K}$ also has finite projective dimension [Sta20, Tag 0A5M]. Furthermore, since $k[\Sigma]$ has finitistic dimension 0 (by RG71, the finitistic dimension of a commutative ring is bounded by the Krull dimension), the projective amplitude of $K$ lies in $[a, b]$. Hence $\mathcal{K}$ is represented by a complex of projective $k[\Sigma]$-modules supported in degrees $[a, b]$, and therefore has tor-amplitude in $[a, b]$.

Definition 3.2.5. Let $\epsilon: \Lambda[\Sigma] \rightarrow \Lambda$ be the augmentation and $\epsilon^{*}: D_{\text {êt }}^{b}(Y ; \Lambda) \rightarrow D_{\text {êt }}^{b}(Y ; \Lambda[\Sigma])$ be pullback along $\epsilon$. Define $\mathbb{T}:=\mathbb{T}^{*} \epsilon^{*}: D_{\text {ett }}^{b}(Y ; \Lambda) \rightarrow \operatorname{Shv}\left(Y ; \mathcal{T}_{\Lambda}\right)$.
Remark 3.2.6. The notation $\mathbb{T}, \mathbb{T}^{*}, \epsilon^{*}$ follows that of Leslie-Lonergan [L21].
3.3. Fixed points. For an endomorphism $\sigma$ of a v-stack $Y$, we write $\operatorname{Fix}(\sigma, Y):=Y^{\sigma}$ for the fibered product

Observe that if $Y$ is a separated locally spatial diamond, then $\Delta$ is a closed embedding, hence $Y^{\sigma} \rightarrow Y$ is a closed embedding. We will only be interested in this situation. We denote by $\Sigma=\langle\sigma\rangle$ the cyclic group of order $\ell$. Recall the equivariant bounded derived category $D_{\text {ett }}^{b}(Y ; \Lambda)^{B \Sigma}$, which is the homotopy category of $\mathcal{D}_{\text {et }}^{b}(Y ; \Lambda)^{B \Sigma}$, the $\infty$-category of functors from $B \Sigma$ to the $\infty$-category $\mathcal{D}_{\text {ét }}^{b}(Y ; \Lambda)$ from [Sch22, §17].

The $\Sigma$-action on $Y$ induces the trivial $\Sigma$-action on $Y^{\sigma}$, for which we have an equivalence of derived categories

$$
\begin{equation*}
D_{\text {êt }}^{b}\left(Y^{\sigma} ; \Lambda\right)^{B \Sigma} \cong D_{\text {êt }}^{b}\left(Y^{\sigma} ; \Lambda[\Sigma]\right) . \tag{3.3}
\end{equation*}
$$

3.4. Bounding tor-dimension. Here we establish technical results that show the "permanence" of finite tor-dimension under various operations.

Lemma 3.4.1. Let $Y$ be a locally spatial diamond with a free action of $\Sigma$. Let $q: Y \rightarrow Y / \Sigma$ denote the quotient. Then for any $\mathcal{F} \in D_{e t}^{b}(Y ; \Lambda[\Sigma])$, we have $q_{*} \mathcal{F} \in \operatorname{Flat}^{b}(Y / \Sigma ; \Lambda[\Sigma]) \subset D_{e t t}^{b}(Y / \Sigma ; \Lambda[\Sigma])$.
Proof. It suffices to show that for any open subset $U \subset Y / \Sigma$, the $\Lambda[\Sigma]$-module $q_{*} \mathcal{F}(U)$ is free. Indeed, since $\Sigma$ acts freely on $Y$ we have

$$
q^{-1}(U)=\coprod_{i \in \mathbf{Z} / \ell \mathbf{Z}}^{\ell} U_{i}
$$

where $q$ maps each $U_{i}$ isomorphically to $U$ and $\sigma$ cyclically permutes $U_{i} \mapsto U_{i+1}$. Then

$$
q_{*} \mathcal{F}(U) \cong \mathcal{F}\left(q^{-1}(U)\right) \cong \prod_{i=1}^{\ell} \mathcal{F}\left(U_{i}\right)
$$

where $\sigma$ acts by sending $\left(f_{i} \in \mathcal{F}\left(U_{i}\right)\right)_{i \in \mathbf{Z} / \ell \mathbf{Z}} \mapsto\left(\sigma^{*}\left(f_{i}\right) \in \mathcal{F}\left(U_{i-1}\right)\right)_{i \in \mathbf{Z} / \ell \mathbf{Z}}$, which is visibly free.

Lemma 3.4.2. Let $Y$ be an $\ell$-bounded, separated, $\omega_{0}$-locally spatial diamond with an action of $\Sigma$. Assume that $Y^{\sigma} \hookrightarrow Y$ is $\omega_{0}$-locally extra small. Let $U:=Y \backslash Y^{\sigma}$ and $j: U \hookrightarrow Y$ be its inclusion into $Y$. Then for any $\mathcal{F} \in D_{\text {ét }}^{b}(Y ; \Lambda[\Sigma])$, we have $i^{*} \mathrm{R} j_{*} \mathcal{F} \in \operatorname{Flat}^{b}\left(Y^{\sigma} ; \Lambda[\Sigma]\right)$.

Proof. Let $Y / \Sigma$ be the quotient diamond; then $Y / \Sigma$ is also $\ell$-bounded, $\omega_{0}$-locally spatial, and $Y^{\sigma} \hookrightarrow Y / \Sigma$ is $\omega_{0}$-locally extra small. Let $i: Y^{\sigma} \hookrightarrow Y$ be the inclusion of the $\Sigma$-fixed points. Since the map $q: Y \rightarrow Y / \Sigma$ is totally ramified over $Y^{\sigma}$, the composition

$$
Y^{\sigma} \xrightarrow{i} Y \xrightarrow{q} Y / \Sigma
$$

is a closed embedding, which we denote $\bar{i}$, and the square

is Cartesian. Hence we have an isomorphism

$$
\begin{equation*}
i^{*} \mathrm{R} j_{*} \mathcal{F} \cong \bar{i}^{*} q_{*} \mathrm{R} j_{*} \mathcal{F} \in D_{\text {ét }}^{b}\left(Y^{\sigma} ; \Lambda[\Sigma]\right) \tag{3.4}
\end{equation*}
$$

From the commutativity of the diagram

we have $\bar{i}^{*} q_{*} \mathrm{R} j_{*} \mathcal{F} \cong \bar{i}^{*} \mathrm{R} \bar{j}_{*} q_{U *} \mathcal{F}$. Now Lemma 3.4.1 implies that $q_{U *} \mathcal{F}$ has finite tor-dimension. The extra smallness hypothesis allows us to apply Corollary 3.1.11 to deduce that $\mathrm{R} \bar{j}_{*} q_{U *} \mathcal{F}$ also has finite tor-dimension, hence $\bar{i}^{*} \mathrm{R} \bar{j}_{*} q_{U *} \mathcal{F}$ also has finite tor-dimension, and then we conclude using (3.4).

Lemma 3.4.3. Retain the notation and assumptions from Lemma 3.4.2, Let $i: Y^{\sigma} \hookrightarrow Y$ be the embedding of $\Sigma$-fixed points (assumed to be $\omega_{0}$-locally extra small). Then for any $\mathcal{F} \in D_{e t}^{b}(Y ; \Lambda)^{B \Sigma}$, the cone of the natural map $i^{!} \mathcal{F} \rightarrow i^{*} \mathcal{F}$ belongs to $\operatorname{Flat}^{b}\left(Y^{\sigma} ; \Lambda[\Sigma]\right)$.

Proof. Let $j: Y \backslash Y^{\sigma} \hookrightarrow Y$. Consider the exact triangle $i_{*}!^{!} \mathfrak{\mathcal { F }} \rightarrow \mathcal{F} \rightarrow j_{*} j^{*} \mathcal{F}$ in $D_{\text {ett }}^{b}(Y ; \Lambda)^{B \Sigma}$. Applying $i^{*}$ to it yields the exact triangle in $D_{\text {et }}^{b}\left(Y^{\sigma} ; \Lambda\right)^{B \Sigma}$,

$$
i^{!} \mathcal{F} \rightarrow i^{*} \mathcal{F} \rightarrow i^{*} \mathrm{R} j_{*} j^{*} \mathcal{F}
$$

Then Lemma 3.4.2 implies that $\operatorname{Cone}\left(i^{!} \mathcal{F} \rightarrow i^{*} \mathcal{F}\right) \cong i^{*} \mathrm{R} j_{*} j^{*} \mathcal{F}$ lies in $\operatorname{Flat}^{b}\left(Y^{\sigma} ; \Lambda[\Sigma]\right)$, as desired.
Lemma 3.4.4. Let $A$ be a finite $\Lambda$-algebra (not necessarily commutativ ${ }^{母}$ ). Let $Y$ and $S$ be locally spatial diamonds, and let $f: Y \rightarrow S$ be a shriekable morphism.
(1) Then $\mathrm{R} f_{!}: D_{e t}^{b}(Y ; A) \rightarrow D_{e t}^{b}(S ; A)$ has cohomological dimension $\leq 3 \operatorname{dim} . \operatorname{trg} f$.
(2) If furthermore $S$ has $\ell$-cohomological dimension $\leq d$ and $f$ is $\omega_{0}$-locally spatial, then $\mathrm{R} f_{*}: D_{e t t}^{b}(Y ; A) \rightarrow$ $D_{e t t}^{b}(S ; A)$ has cohomological dimension $\leq 3 \operatorname{dim} . \operatorname{trg} f+d+1$.
Proof. (1) By the hypothesis that $Y$ and $f$ are locally spatial, we may write $Y \cong \varliminf_{i} Y_{i}$ as a filtered colimit of spatial open subdiamonds $j_{i}: Y_{i} \hookrightarrow Y$. We have by definition [Sch22, p.134-135] that

$$
\mathrm{R} f_{!} \cong \underset{i}{\lim } \mathrm{R}\left(\left.f\right|_{Y_{i}}\right)!j_{i}^{*} .
$$

By [Sch22, Theorem 22.5], each $\mathrm{R}\left(\left.f\right|_{Y_{i}}\right)$ ! has cohomological dimension at most 3dim. $\operatorname{trg} f$. Since $j_{i}^{*}$ is exact and filtered colimits are exact, we deduce that $R f_{!}$also has cohomological dimension at most $3 \mathrm{dim} . \operatorname{trg} f$.
(2) Similarly to (1), we have

$$
\mathrm{R} f_{*} \cong \underset{\mathrm{Rlim}_{i}}{ } \mathrm{R}\left(\left.f\right|_{Y_{i}}\right)_{*} j_{i}^{*}
$$

where now we may arrange the indexing set to be countable, thanks to the hypothesis that $f$ is $\omega_{0}$-locally spatial. Each $\mathrm{R}\left(\left.f\right|_{Y_{i}}\right)_{*} j_{i}^{*}$ has cohomological dimension at most 3dim. $\operatorname{trg} f$ by [Sch22, Theorem 22.5]. Then we bound the cohomological dimension of the derived inverse limit as in the proof of Lemma 3.1.10.

Lemma 3.4.5. Let $A$ be a finite $\Lambda$-algebra (not necessarily commutative). Let $Y$ and $S$ be locally spatial diamonds, and let $f: Y \rightarrow S$ be shriekable.
(1) Then $\mathrm{R} f_{!}: D_{e t t}^{b}(Y ; A) \rightarrow D_{e t t}^{b}(S ; A)$ carries Flat $^{b}(Y ; A)$ to Flat $^{b}(S ; A)$.
(2) If furthermore $S$ is $\ell$-bounded and $f$ is $\omega_{0}$-locally spatial, then $\mathrm{R} f_{*}$ carries $\mathrm{Flat}^{b}(Y ; A)$ to Flat $^{b}(S ; A)$.

Proof. (1) Suppose $\mathcal{F} \in \operatorname{Flat}^{b}(Y ; A)$. We need to verify that for any sheaf $M$ (concentrated in degree 0 ) in $D_{\text {ett }}^{b}(S ; A)$, we have $\mathrm{H}^{-i}(M \stackrel{\mathrm{~L}}{\otimes} \mathrm{R} f!\mathcal{F})=0$ for $i \gg 0$. By the projection formula, we have

$$
\mathrm{H}^{-i}\left(M \stackrel{\mathrm{~L}}{\otimes} A \mathrm{R} f_{!} \mathcal{F}\right) \cong \mathrm{H}^{-i}\left(\mathrm{R} f_{!}\left(f^{*} M \stackrel{\mathrm{~L}}{\otimes_{A}} \mathcal{F}\right)\right) .
$$

By the assumption that $\mathcal{F} \in \operatorname{Flat}^{b}(Y ; A), f^{*} M \stackrel{\mathrm{~L}}{\otimes} A \mathcal{F}$ is bounded. Then by Lemma 3.4.4 $(1), \mathrm{R} f_{!}\left(f^{*} M \stackrel{\mathrm{~L}}{\otimes_{A}} \mathcal{F}\right)$ is bounded, so $\mathrm{H}^{-i}\left(\mathrm{R} f_{!}\left(f^{*} M \stackrel{\mathrm{~L}}{\otimes} A \mathcal{F}\right)\right)=0$ for $i \gg 0$, as desired.
(2) This follows from [SGA73, Exposé XVII, Théorème 5.2.11], which applies because $R f_{*}$ has finite cohomological dimension by Lemma 3.4.4 and the fact Sch22, Proposition 14.3] that $S_{\text {et }}$ has enough points, thanks to $S$ being locally spatial.

Corollary 3.4.6. Let $Y$ and $S$ be locally spatial diamonds, and let $f: Y \rightarrow S$ be shriekable. Suppose $\Sigma$ acts trivially on $S$ and freely on $Y$, and $f$ is $\Sigma$-equivariant.
(1) Then $\mathrm{R} f_{!}: D_{e t}^{b}(Y ; \Lambda[\Sigma]) \rightarrow D_{e t}^{b}(S ; \Lambda[\Sigma])$ lands in $\operatorname{Flat}^{b}(Y ; \Lambda[\Sigma])$.
(2) If furthermore $S$ has $\ell$-cohomological dimension $\leq d$ and $f$ is $\omega_{0}$-locally spatial, then $\mathrm{R} f_{*}$ carries $\operatorname{Flat}^{b}(Y ; \Lambda[\Sigma])$ to $\operatorname{Flat}^{b}(S ; \Lambda[\Sigma])$.

Proof. By the hypotheses, we may factor $f$ as the composition of $\Sigma$-equivariant maps

$$
Y \xrightarrow{q} Y / \Sigma \xrightarrow{\bar{f}} S .
$$

For (1), apply Lemma 3.4.1 to $q$ ! and Lemma 3.4.5 (1) to $\mathrm{R} \bar{f}$ ! with $A:=\Lambda[\Sigma]$. For (2), apply Lemma 3.4.1 to $q_{*}=q_{!}$and Lemma 3.4.5 (2) to $\mathrm{R} \bar{f}_{*}$ with $A:=\Lambda[\Sigma]$.

[^3]3.5. Functors on Tate categories. Let $f: Y \rightarrow S$ denote a $\Sigma$-equivariant map of separated locally spatial diamonds with $\Sigma$-action.
3.5.1. Pullback. Since the pullback functor $f^{*}: D_{\text {êt }}^{b}\left(S^{\sigma} ; \Lambda\right)^{B \Sigma} \rightarrow D_{\text {êt }}^{b}\left(Y^{\sigma} ; \Lambda\right)^{B \Sigma}$ preserves stalks, it carries Flat ${ }^{b}\left(S^{\sigma} ; \Lambda[\Sigma]\right)$ to $\operatorname{Flat}^{b}\left(Y^{\sigma} ; \Lambda[\Sigma]\right)$, hence induces a functor
$$
f^{*}: \operatorname{Shv}\left(S^{\sigma} ; \mathcal{T}_{\Lambda}\right) \rightarrow \operatorname{Shv}\left(Y^{\sigma} ; \mathcal{T}_{\Lambda}\right)
$$
3.5.2. Pushforward. Assume furthermore that $f: Y \rightarrow S$ is shriekable. By Lemma 3.4.5(1), the functor $\mathrm{R} f_{!}: D_{\text {êt }}^{b}\left(Y^{\sigma} ; \Lambda[\Sigma]\right) \rightarrow D_{\text {ett }}^{b}\left(S^{\sigma} ; \Lambda[\Sigma]\right)$ carries Flat $^{b}\left(Y^{\sigma} ; \Lambda[\Sigma]\right)$ to Flat $^{b}\left(S^{\sigma} ; \Lambda[\Sigma]\right)$, hence induces a functor
$$
\mathrm{R} f_{!}: \operatorname{Shv}\left(Y^{\sigma} ; \mathcal{T}_{\Lambda}\right) \rightarrow \operatorname{Shv}\left(S^{\sigma} ; \mathcal{T}_{\Lambda}\right)
$$

If $f$ is furthermore $\omega_{0}$-locally spatial and $i: Y^{\sigma} \hookrightarrow Y$ is $\omega_{0}$-locally extra small, then similarly using Lemma 3.4.5 (2) gives a functor

$$
\operatorname{R} f_{*}: \operatorname{Shv}\left(Y^{\sigma} ; \mathcal{T}_{\Lambda}\right) \rightarrow \operatorname{Shv}\left(S^{\sigma} ; \mathcal{T}_{\Lambda}\right)
$$

3.6. The Smith operation. We define the analogue in $p$-adic geometry of the "Smith operation" Psm introduced by Treumann in Tre19.

Definition 3.6.1. Let $Y$ be a separated locally spatial diamond with an action of $\Sigma$ and $i: Y^{\sigma} \hookrightarrow Y$ the inclusion of its $\Sigma$-fixed points. The Smith operation is the functor

$$
\begin{equation*}
\operatorname{Psm}:=\mathbb{T}^{*} \circ i^{*}: D_{\text {êt }}^{b}(Y ; \Lambda)^{B \Sigma} \rightarrow \operatorname{Shv}\left(Y^{\sigma} ; \mathcal{T}_{\Lambda}\right) \tag{3.5}
\end{equation*}
$$

defined as the composition of $i^{*}: D_{\text {ét }}^{b}(Y ; \Lambda)^{B \Sigma} \rightarrow D_{\text {êt }}^{b}\left(Y^{\sigma} ; \Lambda\right)^{B \Sigma} \stackrel{\sqrt{3.3}}{=} D_{\text {ét }}^{b}\left(Y^{\sigma} ; \Lambda[\Sigma]\right)$ with the projection $\mathbb{T}^{*}$ to $\operatorname{Shv}\left(Y^{\sigma} ; \mathcal{T}_{\Lambda}\right)$.

The following result may be viewed as a form of equivariant localization for spaces with $\Sigma$-action, comparing the (relative) cohomology of a space with that of its $\Sigma$-fixed points.

Proposition 3.6.2. Let $Y$ and $S$ be separated locally spatial diamonds, and let $f: Y \rightarrow S$ be shriekable. Denote be $f^{\sigma}: Y^{\sigma} \rightarrow S^{\sigma}$ the induced map on fixed points.
(1) Then the following diagram commutes:

(2) If $f$ is $\omega_{0}$-locally spatial and $i: Y^{\sigma} \hookrightarrow Y$ is $\omega_{0}$-locally extra small, then the following diagram commutes:

Proof. For both statements, we may replace $S$ by $S^{\sigma}$ and therefore assume that the $\Sigma$-action on $S$ is trivial.
(1) Let $\mathcal{F} \in D_{\text {êt }}^{b}(Y ; \Lambda)^{B \Sigma}$. Writing $j:\left(Y \backslash Y^{\sigma}\right) \hookrightarrow Y$ for the open complement of $i: Y^{\sigma} \hookrightarrow Y$, we have an exact triangle

$$
j!j^{*} \mathcal{F} \rightarrow \mathcal{F} \rightarrow i_{*} i^{*} \mathcal{F} \in D_{\text {êt }}^{b}(Y ; \Lambda)^{B \Sigma}
$$

By definition $\Sigma$ acts freely on $U$, which by Lemma 3.4.5 (1) implies that $\operatorname{R} f_{!} \circ\left(j!j^{*} \mathcal{F}\right) \in \operatorname{Flat}^{b}(S ; \Lambda[\Sigma])$. Hence the cone of $\mathrm{R} f_{!} \mathcal{F} \rightarrow \mathrm{R} f_{!}^{\sigma}\left(i^{*} \mathcal{F}\right)$ lies in $\operatorname{Flat}^{b}(S ; \Lambda[\Sigma])$, and therefore becomes 0 in $\operatorname{Shv}\left(S ; \mathcal{T}_{\Lambda}\right)$. Therefore

$$
\mathbb{T}^{*}\left(\mathrm{R} f_{!} \mathcal{F}\right) \cong \mathbb{T}^{*}\left(\mathrm{R} f_{!}^{\sigma}\left(i^{*} \mathcal{F}\right)\right) \cong \mathrm{R} f_{!}^{\sigma} \operatorname{Psm}(\mathcal{F}) \in \operatorname{Shv}\left(S ; \mathcal{T}_{\Lambda}\right)
$$

which exactly expresses the desired commutativity.
(2) The argument is similar to that for (1), but using instead the exact triangle

$$
i_{*} i^{!} \mathcal{F} \rightarrow \mathcal{F} \rightarrow j_{*} j^{*} \mathcal{F}
$$

By Lemma 3.4.5 (2), the cone of $\mathrm{R} f_{*} i_{*} i^{!} \mathcal{F} \rightarrow \mathrm{R} f_{*} \mathcal{F}$ lies in $\mathrm{Flat}^{b}(S ; \Lambda[\Sigma])$, and therefore projects to 0 in $\operatorname{Shv}\left(S ; \mathcal{T}_{\Lambda}\right)$. Then using Lemma 3.4.3 the maps $\mathrm{R} f_{*} i_{*} i^{!} \mathcal{F} \rightarrow \mathrm{R} f_{*} i_{*} i^{*} \mathcal{F} \rightarrow \mathrm{R} f_{*} \mathcal{F}$ project to isomorphisms in $\operatorname{Shv}\left(S ; \mathcal{T}_{\Lambda}\right)$.
3.7. Tate cohomology. For a $\Lambda[\Sigma]$-module $M$, its Tate cohomology groups were defined in (1.1). We extend the definition 2-periodically to define $\mathrm{T}^{j}(M)$ for all $j \in \mathbf{Z}$.

Example 3.7.1 (Tate cohomology of trivial coefficients). Equip $k$ with the trivial $\Sigma$-action. Then we have

$$
\mathrm{T}^{j}(k) \cong k \text { for all } j \in \mathbf{Z}
$$

Equip $\mathbb{O}$ with the trivial $\Sigma$-action. Then we have

$$
\mathrm{T}^{j}(\mathbb{O}) \cong\left\{\begin{array}{lll}
k & j \equiv 0 & (\bmod 2) \\
0 & j \equiv 1 & (\bmod 2)
\end{array}\right.
$$

Example 3.7.2. Let $V$ be a $k$-vector space. Then $V^{\otimes \ell}$ has an action of $\Sigma$, where $\sigma$ acts by cyclic rotation of the factors, and a straightforward calculation shows that

$$
\mathrm{T}^{0}\left(V^{\otimes \ell}\right) \cong V^{(\ell)}:=V \otimes_{k, \operatorname{Frob}_{\ell}} k
$$

the Frobenius twist of $V$.
Next we consider generalizations of Tate cohomology to complexes and sheaves.
3.7.1. Tate cohomology of complexes. The Tate cohomology of a complex of $\Lambda[\Sigma]$-modules is defined in Fen, $\S 3.4 .1]$. We summarize below. The exact sequence of $\Lambda[\Sigma]$-modules

$$
0 \rightarrow \Lambda \rightarrow \Lambda[\Sigma] \xrightarrow{1-\sigma} \Lambda[\Sigma] \rightarrow \Lambda \rightarrow 0
$$

induces a morphism

$$
\begin{equation*}
\Lambda \rightarrow \Lambda[2] \in D^{b}(\Lambda[\Sigma]) \tag{3.6}
\end{equation*}
$$

Note that it becomes an isomorphism in the Tate category $D^{b}(\Lambda[\Sigma]) / \operatorname{Flat}^{b}(\Lambda[\Sigma])$, since the middle two terms project to 0 . Given a bounded-below complex of $\Lambda[\Sigma]$-modules $C^{\bullet}$, we define its Tate cohomology as

$$
\mathrm{T}^{n}\left(C^{\bullet}\right)=\underset{j \rightarrow \infty}{\lim } \operatorname{Hom}_{D^{+}(\Lambda[\Sigma])}\left(\Lambda, C^{\bullet}[n+2 j]\right)
$$

where the transition maps are those induced by (3.6). Evidently $\mathrm{T}^{n}\left(C^{\bullet}\right)$ is 2-periodic in $n$, and we occasionally view the indexing as being $n \in \mathbf{Z} / 2 \mathbf{Z}$. It is clear that this construction descends to the derived category.

Now we state some assertions that may be specific ${ }^{5}$ to $\Lambda=k$. By [Sta20, Tag 051E], a module over $k[\Sigma]$ is flat if and only if it is free. Since Tate cohomology of free $k[\Sigma]$-complexes vanishes (by inspection), this construction further factors through the Tate category, inducing

$$
\mathrm{T}^{n}: \operatorname{Shv}\left(\mathrm{pt} ; \mathcal{T}_{k}\right) \rightarrow \operatorname{Vect}_{/ k}
$$

We write $\mathrm{T}^{*}:=\bigoplus_{n} \mathrm{~T}^{n}$ and $\mathrm{H}^{*}:=\bigoplus_{n} \mathrm{H}^{n}$.
Remark 3.7.3 (Tate cohomology as Hom in the Tate category). If $C^{\bullet} \in D^{b}(k[\Sigma])$ is bounded, then the argument of [LL21, Proposition 4.5.1] gives a natural isomorphism

$$
\mathrm{T}^{i}\left(C^{\bullet}\right) \cong \operatorname{Hom}_{\operatorname{Shv}\left(\mathrm{pt} ; \mathcal{T}_{k}\right)}\left(k, \mathbb{T}^{*} C^{\bullet}[i]\right)
$$

Example 3.7.4 (Tate cohomology of trivial complexes). If $C^{\bullet} \in D^{b}(\mathbb{O})$, then (cf. Definition 3.2.5 for notation) we have

$$
\mathrm{T}^{*}\left(\epsilon^{*} C^{\bullet}\right) \cong \mathrm{H}^{*}\left(\operatorname{Tot}\left(\ldots \xrightarrow{\ell} C^{\bullet} \xrightarrow{0} C^{\bullet} \xrightarrow{\ell} C^{\bullet} \xrightarrow{0} \ldots\right)\right)
$$

so that

$$
\mathrm{T}^{n}\left(\epsilon^{*} C^{\bullet}\right) \cong \bigoplus_{i \equiv n} \mathrm{H}^{i}\left(C^{\bullet} \stackrel{\mathrm{mod} 2)}{\mathrm{L}} \underset{\mathbb{O}}{ } k\right)
$$

[^4]If $C^{\bullet} \in D^{b}(k)$, then we have

$$
\begin{equation*}
\mathrm{T}^{*}\left(\epsilon^{*} C^{\bullet}\right) \cong \mathrm{H}^{*}\left(C^{\bullet}\right) \otimes_{k} \mathrm{~T}^{*}(k) \tag{3.7}
\end{equation*}
$$

where $k$ is equipped with the trivial $\Sigma$-action. By Example 3.7.1, (3.7) simplifies to

$$
\mathrm{T}^{n}\left(\epsilon^{*} C^{\bullet}\right) \cong \bigoplus_{i \in \mathbf{Z}} \mathrm{H}^{i}\left(C^{\bullet}\right)
$$

3.7.2. Tate cohomology sheaves. Let $S$ be a locally spatial diamond with trivial $\Sigma$-action, so that $\operatorname{Shv}\left(S ; \mathcal{T}_{\Lambda}\right)$ is defined. Given $\mathcal{F} \in D_{\text {êt }}^{b}(S ; \Lambda[\Sigma])$, we define Tate cohomology sheaves

$$
\mathrm{T}^{n}(\mathcal{F}):=\underset{j \rightarrow \infty}{\lim _{j \rightarrow}} \mathcal{H o m}_{D_{\mathrm{et}}^{b}(S ; \Lambda[\Sigma])}(\Lambda, \mathcal{F}[n+2 j])
$$

where the transition maps are induced by (3.6). The $\mathrm{T}^{i}(\mathcal{F})$ are étale sheaves of $T^{0}(\Lambda)$-modules, where $T^{0}(\Lambda)$ is the 0th Tate cohomology of the trivial $\Sigma$-module $\Lambda$.

Remark 3.7.5. For $\Lambda=k$, as in Remark 3.7.3 we also have the description

$$
\mathrm{T}^{i}(\mathcal{F}) \cong \mathcal{H o m}_{\mathrm{Shv}\left(S ; \mathcal{T}_{k}\right)}\left(k, \mathbb{T}^{*} \mathcal{F}[i]\right)
$$

3.7.3. Tate cohomology for a morphism. Assume that $Y$ and $S$ are separated locally spatial diamonds with an action of $\Sigma$, and $f: Y \rightarrow S$ is a $\Sigma$-equivariant shriekable morphism.

For $\mathcal{F} \in D_{\text {êt }}^{b}(Y ; \Lambda)^{B \Sigma}$, we have $\mathrm{R} f_{!}(\mathcal{F}) \in D_{\text {ett }}^{b}(S ; \Lambda)^{B \Sigma}$. If $S$ has the trivial $\Sigma$-action, then we can form the "relative Tate cohomology" sheaves $\mathrm{T}^{n}\left(\mathrm{R} f_{!} \mathcal{F}\right)$ on $S$.

Remark 3.7.6. Note that if $\Sigma$ acts trivially on $Y$ and on $S$, then the construction $\mathcal{F} \mapsto \mathrm{R} f_{!}(\mathcal{F})$ factors over $\operatorname{Shv}\left(Y ; \mathcal{T}_{k}\right)$ by Lemma 3.4.5. In this situation we will also regard $\mathrm{T}^{i}\left(\mathrm{R} f_{!}\right)$as a functor on $\operatorname{Shv}\left(Y ; \mathcal{T}_{k}\right)$.
3.7.4. The long exact sequence for Tate cohomology. Let assumptions be as in $\$ 3.7 .3$, and suppose furthermore that the $\Sigma$-action on $S$ is trivial. Given a distinguished triangle $\mathcal{F}^{\prime} \rightarrow \mathcal{F} \rightarrow \mathcal{F}^{\prime \prime} \in D_{\text {ét }}^{b}(Y ; \Lambda)^{B \Sigma}$, we have a long exact sequence of étale sheaves on $S$,

$$
\begin{aligned}
& \ldots \longrightarrow \mathrm{T}^{-1}\left(\mathrm{R} f_{!}\left(\mathcal{F}^{\prime \prime}\right)\right) \\
& \longrightarrow \mathrm{T}^{0}\left(\mathrm{R} f_{!}\left(\mathcal{F}^{\prime}\right)\right) \longrightarrow \mathrm{T}^{0}\left(\mathrm{R} f_{!}(\mathcal{F})\right) \longrightarrow \mathrm{T}^{0}\left(\mathrm{R} f_{!}\left(\mathcal{F}^{\prime \prime}\right)\right) \\
& \longrightarrow \mathrm{T}^{1}\left(\mathrm{R} f_{!}\left(\mathcal{F}^{\prime}\right)\right) \longrightarrow
\end{aligned}
$$

## 4. $\Sigma$-FIXED POINT CALCULATIONS

Let $G$ be a reductive group over $E$ and $\sigma$ an order $\ell \neq p$ automorphism of $G$ such that $H:=G^{\sigma}$ is (connected) reductive.

Example 4.0.1. By [FS21, Theorem VIII.5.14] and Ste68, Theorem 8.1], $H$ is automatically (connected) reductive if $G$ is semisimple simply connected.

In this section we will analyze the fixed points of $\sigma$ on various spaces affiliated with $G$, and relate them to spaces affiliated with $H$, such as:

- The $\mathrm{B}_{\mathrm{dR}}^{+}$-affine Grassmannians, as well as their variants such as Beilinson-Drinfeld affine Grassmannians, convolution affine Grassmannians, and "twisted" affine Grassmannians (which are the target of the generalized Grothendieck-Messing period maps).
- The moduli stacks of local shtukas.

These calculations are used later when applying Smith-Treumann localization to such spaces.
4.1. Affine Grassmannians. We begin by formulating the results for affine Grassmannians and their variants.
Proposition 4.1.1. Let $\mathbf{C}$ be an algebraically closed field. Let $\mathrm{Gr}_{G, \mathbf{C}}^{\mathrm{alg}}, \mathrm{Gr}_{H, \mathbf{C}}^{\mathrm{alg}}$ be the algebraic affine Grassmannians over $\mathbf{C}$. Then the map $\mathrm{Gr}_{H, \mathbf{C}}^{\mathrm{alg}} \rightarrow \operatorname{Fix}\left(\sigma, \mathrm{Gr}_{G, \mathbf{C}}^{\mathrm{alg}}\right)$ is an isomorphism on underlying reduced indschemes.

The proof of Proposition 4.1.1 will be given shortly below, in 4.1.1. For now we assume it and deduce a few consequences for mixed-characteristic Beilinson-Drinfeld Grassmannians.

Let $S$ be a separated locally spatial diamond over $\left(\operatorname{Div}_{X}^{1}\right)^{I}$. Then we define

$$
\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}:=\operatorname{Gr}_{G,\left(\operatorname{Div}_{X}^{1}\right)^{I}} \times{ }_{\left(\operatorname{Div}_{X}^{1}\right)^{I}} S .
$$

Proposition 4.1.2. Let $S$ be a separated locally spatial diamond over $\left(\operatorname{Div}_{X}^{1}\right)^{I}$. Then the natural map

$$
\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} \rightarrow \operatorname{Fix}\left(\sigma, \operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}\right)
$$

is an isomorphism on underlying reduced ind-schemes.
Proof. Since $\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}$ is separated, $\operatorname{Fix}\left(\sigma, \operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}\right)$ is a closed subdiamond of $\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}$. The map $\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} \rightarrow \operatorname{Fix}\left(\sigma, \operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}\right)$ is a closed embedding by the argument of SW20, Lemma 19.1.5], hence qcqs, so by Sch22, Lemma 11.11] it is an isomorphism if and only if it induces a bijection on $\mathrm{Spa}\left(C, C^{+}\right)$-points for all $\left(C, C^{+}\right)$. Checking this reduces to the case where $S=\mathrm{Spa}\left(C, C^{+}\right)$, in which case we abbreviate $\mathrm{Gr}_{G, C}:=\operatorname{Gr}_{G, \mathrm{Spa}\left(C, C^{+}\right) /\left(\operatorname{Div}_{X}^{1}\right)^{I}}$ and similarly for $H$.

A Spa $\left(C, C^{+}\right)$-point of $\operatorname{Gr}_{G, C}$ consists of $|I|$ untilts $\left\{C_{i}^{\sharp} / E\right\}_{i \in I}$, and for each $i \in I$ a $\left(C_{i}^{\sharp}, \mathcal{O}_{C_{i}^{\sharp}}\right)$-point of $\mathrm{Gr}_{G}^{\mathrm{B}_{d \mathrm{R}}^{+}}$, the $\mathrm{B}_{\mathrm{dR}}^{+}$-affine Grassmannian built using $C_{i}^{\sharp}$ as discussed in [SW20, Lecture XIX]. Any choice of uniformizer $\xi$ for $\mathrm{B}_{\mathrm{dR}}\left(C_{i}^{\sharp}\right)$ induces an isomorphism $\mathrm{B}_{\mathrm{dR}}\left(C_{i}^{\sharp}\right) \cong C_{i}^{\sharp}((\xi)$ ), which induces (cf. [SW20, proof of Proposition 19.2.1]) a commutative diagram

By Proposition 4.1.1 the map $\operatorname{Gr}_{H, C_{i}^{\sharp}}^{\text {alg }}\left(C_{i}^{\sharp}\right) \rightarrow \operatorname{Fix}\left(\sigma, \operatorname{Gr}_{G, C_{i}^{\sharp}}^{\text {alg }}\right)\left(C_{i}^{\sharp}\right)$ is a bijection, hence so is the parallel map in the top row. Hence the map

$$
\operatorname{Gr}_{H, C}\left(C, C^{+}\right) \rightarrow \operatorname{Fix}\left(\sigma, \operatorname{Gr}_{G, C}\right)\left(C, C^{+}\right)
$$

is also a bijection, as desired.
Remark 4.1.3. The same argument works for variants like $\left(\operatorname{Div}_{\mathcal{Y}}^{1}\right)^{I}$ instead of $\left(\operatorname{Div}_{X}^{1}\right)^{I}$.
We also deduce variants for convolution Grassmannians and the "twisted" Grassmannians $\operatorname{Gr}_{G}^{\text {tw }}$ from [SW20, §23.5].

Corollary 4.1.4. Let $m \in \mathbf{Z}_{\geq 1}$.
(1) Let $\mathbf{C} / E$ be an algebraically closed field. Let $\widetilde{\operatorname{Gr}}_{G, \mathbf{C}}^{\text {alg,( } m)}$ be the $m$-step convolution Grassmannian for $G$, and similarly for $H$. Then the natural map

$$
\widetilde{\operatorname{Gr}}_{H, \mathbf{C}}^{\mathrm{alg},(m)} \rightarrow \operatorname{Fix}\left(\sigma, \widetilde{\operatorname{Gr}}_{G, \mathbf{C}}^{\mathrm{alg},(m)}\right)
$$

is an isomorphism.
(2) Let I be a finite non-empty set and let $S$ be a separated locally spatial diamond with a map $S \rightarrow$ $\left(\operatorname{Div}_{X}^{1}\right)^{I}$. Let $\widetilde{\operatorname{Gr}}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}^{(m)}$ be the $m$-step convolution Beilinson-Drinfeld Grassmannian for $G$, and similarly for $H$. Then the natural map

$$
\widetilde{\operatorname{Gr}}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}^{(m)} \rightarrow \operatorname{Fix}\left(\sigma, \widetilde{\operatorname{Gr}}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}^{(m)}\right)
$$

is an isomorphism.
(3) Let I be a finite non-empty set. Let $\operatorname{Gr}_{G, I}^{\mathrm{tw}}=\xrightarrow{\lim } \mu_{\bullet} \operatorname{Gr}_{G, \Pi_{i \in I}}^{\mathrm{tw}} \operatorname{Spd} E_{i}, \leq \mu \bullet$ be the twisted affine Grassmannian (cf. [SW20, Definition 23.5.1]). Then the natural map

$$
\operatorname{Gr}_{H, I}^{\mathrm{tw}} \xrightarrow{\sim} \operatorname{Fix}\left(\sigma, \operatorname{Gr}_{G, I}^{\mathrm{tw}}\right)
$$

is an isomorphism.

Proof. (1) The map $\widetilde{\operatorname{Gr}}_{G}^{\mathrm{alg},(m)} \rightarrow\left(\operatorname{Gr}_{G}^{\text {alg }}\right)^{m}$ sending $\left(\mathcal{E}^{0} \longrightarrow \mathcal{E}_{1} \rightarrow \ldots \mathcal{E}_{m}\right)$ to $\left(\mathcal{E}^{0} \ldots \mathcal{E}_{1}, \mathcal{E}^{0} \rightarrow\right.$ $\left.\mathcal{E}_{2}, \ldots, \mathcal{E}^{0} \rightarrow \mathcal{E}_{m}\right)$ is a $\Sigma$-equivariant isomorphism. Under this isomorphism, the statement transports to (the $m$ th power of) that of Proposition 4.1.1.
(2) As in the proof of Proposition 4.1.2 the statement reduces to the case where $S=\operatorname{Spa}\left(C, C^{+}\right)$. Then as in the proof of Proposition 4.1.2, the statement follows from the algebraic case over untilts $C^{\sharp}$ of $C$, which were treated in (1).
(3) As in the proof of Proposition 4.1.4, the statement reduces to the case $S=\mathrm{Spa}\left(C, C^{+}\right)$, where it is then a consequence of (2).
4.2. Borels. Recall that a Borus of a reductive group $G$ is a pair $(B, T)$ of a Borel subgroup $B<G$ and a split maximal torus $T<B$.

Lemma 4.2.1. Suppose $\Sigma$ stabilizes a Borus $(B, T)$ of $G$. Then $\left(B^{\sigma}, T^{\sigma}\right)$ is a Borus of $H$.
Proof. Suppose for the moment that we have shown $B^{\sigma}$ is a Borel subgroup of $H$. We will argue that $T^{\sigma}$ is a maximal torus of $H$. Let $U$ be the unipotent radical of $B$. Applying [CGP15, Proposition A.8.10(2)], which implies that the map on $\Sigma$-fixed points of a smooth $\Sigma$-equivariant morphism is again smooth, to $B \rightarrow$ $B / U \cong T$ shows that $B^{\sigma} \rightarrow(B / U)^{\sigma} \cong T^{\sigma}$ is a smooth map whose non-empty fibers are $U^{\sigma}$-torsors. Since the section $T^{\sigma} \hookrightarrow B^{\sigma}$ shows that $B^{\sigma} \rightarrow T^{\sigma}$ is surjective, we conclude that the map $B^{\sigma} / U^{\sigma} \rightarrow(B / U)^{\sigma} \cong T^{\sigma}$ is an isomorphism. This shows that $T^{\sigma}$ is a maximal torus of $H$ (and in particular is connected).

Now we complete the proof by showing that $H / B^{\sigma}$ is projective. Since $B^{\sigma}$ is clearly solvable, in order to show that it is a Borel subgroup of $H$ it suffices by a result of Chevalley [Con, Theorem 1.3.1] to show that it is parabolic, i.e., that $G^{\sigma} / B^{\sigma}$ is projective. By assumption $G / B$ is projective, hence its closed subscheme $(G / B)^{\sigma}$ is projective. We will prove that $H / B^{\sigma}$ is closed and open in $(G / B)^{\sigma}$, which will imply that $H / B^{\sigma}$ is projective. Evidently $H$ acts by translation on $(G / B)^{\sigma}$, and it suffices to show that each $H$-orbit in $(G / B)^{\sigma}$ is open, since then the orbits are finite in number and pairwise disjoint, hence comprise the connected components. Indeed, for any geometric point $g$ of $G$ representing a point in $(G / B)^{\Sigma}$, the orbit $\operatorname{map} G^{\sigma} \rightarrow(G / B)^{\sigma}$ through $g B$ is a smooth morphism by [CGP15, Proposition A.8.10(2)] again, hence has open image.

Proposition 4.2.2. Let $S$ be a seaparated locally spatial diamond over $\left(\operatorname{Div}_{X}^{1}\right)^{I}$. Suppose that $G$ has a $\Sigma$-stable Borel subgroup B. Let $B_{H}:=B^{\sigma}$, a Borel subgroup of $H$ by Lemma4.2.1. Then the natural map

$$
\operatorname{Gr}_{B_{H}, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} \rightarrow \operatorname{Fix}\left(\sigma, \operatorname{Gr}_{B, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}\right)
$$

is an isomorphism.
Proof. The map $\operatorname{Gr}_{B, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} \rightarrow \operatorname{Fix}\left(\sigma, \operatorname{Gr}_{\left.B, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}\right)}\right.$ is a closed embedding by the same argument as SW20, Lemma 19.1.5], hence qcqs, so by Sch22, Lemma 11.11] it suffices to check that it induces a bijection on geometric points. A variation on [FS21, Proposition VI.3.1] shows that the maps $\mathrm{Gr}_{B_{H}, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} \rightarrow$ $\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}$ and $\operatorname{Gr}_{B, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} \rightarrow \operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}$ are bijections on geometric points. Hence in the commutative diagram

both vertical maps and the bottom horizontal map induce bijections on geometric points (the latter by Proposition 4.1.2. Therefore the upper horizontal map also induces a bijection on geometric points, concluding the proof.
4.3. Proof of Proposition 4.1.1. We write $L G^{\text {alg }}$ for the loop group of $G$ with respect to the loop variable $t$, so $L G^{\text {alg }}(R)=G(R((t)))$. We write $L^{+} G^{\text {alg }} \subset L G^{\text {alg }}$ for the arc group, with functor of points $L^{+} G^{\text {alg }}(R)=$ $G(R[t t])$. The algebraic affine Grassmannian is the fppf quotient $L G^{\text {alg }} / L^{+} G^{\text {alg }}$, which has a natural indscheme structure.

For the purpose of proving Proposition 4.1.1, we may base change $G$ to the algebraically closed field $\mathbf{C}$. Since $\sigma$ is a semisimple automorphism of $G$ over an algebraically closed field, a theorem of Steinberg [Ste68, Theorem 7.5] implies that $\sigma$ stabilizes a Borus $(B, T)$ of $G$. By Lemma 4.2.1, $\left(B^{\sigma}, T^{\sigma}\right)$ is Borus of $H:=G^{\sigma}$.
4.3.1. Iwahori stratification. Let $\mathrm{Iw}^{G}$ be the Iwahori subgroup of $L^{+} G$ corresponding to $B$. This induces a stratification by $\mathrm{Iw}^{G}$-orbits (cf. [RW22, (4.6)])

$$
\mathrm{Gr}_{G, \mathbf{C}}^{\mathrm{alg}, \mathrm{red}}=\coprod_{\lambda \in X_{*}(T)} \mathrm{Gr}_{G, \lambda}^{\mathrm{alg}}
$$

Furthermore, $\mathrm{Iw}^{G}$ is stable under $\sigma$ and $\mathrm{Iw}^{H}:=\left(\mathrm{Iw}^{G}\right)^{\sigma}$ is the Iwahori subgroup of $L^{+} H$ corresponding to $B^{\sigma}$, so we have an analogous stratification

$$
\mathrm{Gr}_{H, \mathbf{C}}^{\text {alg,red }}=\coprod_{\lambda \in X_{*}\left(T^{\sigma}\right)} \mathrm{Gr}_{H, \lambda}^{\mathrm{alg}}
$$

The action of $\sigma$ on $G$ induces an action on $X_{*}(T)$. We will show that:
(1) If $\lambda$ is not fixed by $\sigma$, then $\operatorname{Gr}_{G, \lambda}^{\mathrm{alg}} \cap\left(\sigma \cdot \mathrm{Gr}_{G, \lambda}^{\mathrm{alg}}\right)=\emptyset$.
(2) If $\lambda$ is fixed by $\sigma$, then $\operatorname{Fix}\left(\sigma, \operatorname{Gr}_{G, \lambda}^{\text {alg }}\right) \stackrel{\sim}{\leftarrow} \operatorname{Gr}_{H, \lambda}^{\text {alg }}$.

The combination of (1) and (2) clearly suffices to prove Proposition 4.1.1.
Item (1) is immediate: since we arranged $\sigma$ to preserve $\mathrm{Iw}^{G}$, we have $\sigma \cdot \operatorname{Gr}_{G, \lambda}=\operatorname{Gr}_{G, \sigma(\lambda)}$. As distinct $\mathrm{Iw}^{G}$-orbits are disjoint, the intersection of any two distinct $\mathrm{Iw}^{G}$-orbits is empty.

Next we turn to (2). For this we analyze the structure of the strata.
4.3.2. Fixed points of strata. For any root $\alpha \in \mathfrak{R}$, let $U_{\alpha} \subset G$ be the corresponding root subgroup. For an affine root $\alpha+m \hbar$ of $G$, denote by $U_{\alpha+m \hbar}$ the corresponding subgroup of $L G$ (cf. [RW22, §4.3]), which for any isomorphism $u_{\alpha}: \mathbf{G}_{a} \xrightarrow{\sim} U_{\alpha}$, identifies with the image of $x \mapsto u_{\alpha}\left(x t^{m}\right)$. Set

$$
\delta_{\alpha}:= \begin{cases}1 & \alpha \in \mathfrak{R}^{+} \\ 0 & \text { otherwise }\end{cases}
$$

and for $\lambda \in X_{*}(T)$ define

$$
\begin{equation*}
\operatorname{Iw}_{\mathrm{u}}^{G, \lambda}:=\prod_{\alpha \in \mathfrak{R}}\left(\prod_{\delta_{\alpha} \leq m<\langle\lambda, \alpha\rangle} U_{\alpha+m \hbar}\right) \tag{4.1}
\end{equation*}
$$

where the product may be taken in any order. Then as explained in the proof of [RW22, Lemma 4.4], the action of $\operatorname{Iw}_{\mathrm{u}}^{G, \lambda}$ on $t^{\lambda} \in \operatorname{Gr}_{G}(\mathbf{C})$ induces an isomorphism

$$
\begin{equation*}
\mathrm{Iw}_{\mathrm{u}}^{G, \lambda} \xrightarrow{\sim} \mathrm{Gr}_{G, \lambda}^{\mathrm{alg}} . \tag{4.2}
\end{equation*}
$$

Suppose $\sigma$ fixes $\lambda$. Then 4.2 implies that

$$
\operatorname{Fix}\left(\sigma, \operatorname{Gr}_{G, \lambda}^{\mathrm{alg}}\right)=\left(\operatorname{Iw}_{\mathrm{u}}^{G, \lambda}\right)^{\sigma} \cdot t^{\lambda}
$$

Denote by $\operatorname{Iw}_{\mathrm{u}}^{G, \lambda}(\alpha)$ the factor of $\operatorname{Iw}_{\mathrm{u}}^{G, \lambda}$ in 4.1) indexed by $\alpha$. If $\sigma(\alpha) \neq \alpha$, then $\operatorname{Iw}_{\mathrm{u}}^{G, \lambda}(\alpha)^{\sigma}=0$. On the other hand, if $\sigma \alpha=\alpha$ then (since $\sigma$ was arranged to preserve $\mathfrak{R}^{+}$) we have $\operatorname{Iw}_{\mathrm{u}}^{G, \lambda}(\alpha)^{\sigma}=\operatorname{Iw}_{\mathrm{u}}^{H, \lambda}(\alpha)$, so that

$$
\left(\operatorname{Iw}_{\mathrm{u}}^{G, \lambda}\right)^{\sigma} \cdot t^{\lambda} \cong \prod_{\alpha \in \mathfrak{R}^{\sigma}} \operatorname{Iw}_{\mathrm{u}}^{H, \lambda}(\alpha) \cong \mathrm{Gr}_{H, \lambda}^{\mathrm{alg}} .
$$

This completes the proof of Proposition 4.1.1.
4.4. Moduli of local shtukas. We now turn to examine the moduli stacks of local shtukas, for which a reference is Scholze's Berkeley lectures, especially [SW20, Lecture XXIII].

Let $\left(G, b,\left\{\mu_{i}\right\}_{i \in I}\right)$ be a local shtuka datum (cf. [SW20, Definition 23.1.1], except we allow the equal characteristic case as well): $G$ is a reductive group over $E, b \in B(G)$, and $\mu_{i}$ is a conjugacy class of cocharacters $\mathbf{G}_{m} \rightarrow G_{E^{s}}$. For any compact open subgroup $K \subset G(E)$ there is a moduli space of local shtukas with $K$-level structure $\operatorname{Sht}_{\left(G, b,\left\{\mu_{i}\right\}_{i \in I}\right), K}$, which is functorial in $K$. There is a moduli description of $\operatorname{Sht}_{\left(G, b,\left\{\mu_{i}\right\}_{i \in I}\right), K}$ given (in the mixed characteristic case) in [SW20, §23].

For $\left\{\mu_{i}\right\}_{i \in I} \leq\left\{\mu_{i}^{\prime}\right\}_{i \in I}$ in the component-wise Bruhat order, there are closed embeddings $\operatorname{Sht}_{\left(G, b,\left\{\mu_{i}\right\}\right), K} \hookrightarrow$ $\operatorname{Sht}_{\left(G, b,\left\{\mu_{i}^{\prime}\right\}\right), K}$. It will also be convenient to consider the following variant without any cocharacter "bounds":

Definition 4.4.1. We define $\operatorname{Sht}_{(G, b, I), K}:={\underset{\longrightarrow}{\left.\lim _{i \mu_{i}}\right\}_{i \in I}}} \operatorname{Sht}_{\left(G, b,\left\{\mu_{i}\right\}_{i \in I}\right), K}$.
4.4.1. Grothendieck-Messing period map. We recall some facts about the generalized Grothendieck-Messing period map

$$
\begin{equation*}
\pi_{\mathrm{GM}}: \operatorname{Sht}_{(G, b, I), K} \rightarrow \operatorname{Gr}_{G, I}^{\mathrm{tw}} \tag{4.3}
\end{equation*}
$$

from [SW20, §23.5]. Note that we have not imposed any "bound" above; our 4.3) comes from the colimit over $\left\{\mu_{i}\right\}_{i \in I}$ of the map from SW20, Corollary 23.5.3].

The image of $\pi_{\mathrm{GM}}$ is an open subset of $\mathrm{Gr}_{G, I}^{\mathrm{tw}, a} \subset \mathrm{Gr}_{G, I}^{\mathrm{tw}}$ called the admissible locus. In terms of points, $\mathrm{Gr}_{G, I}^{\mathrm{tw}}$ parametrizes $G$-torsors $\mathcal{P}_{\eta}$ on $\mathcal{Y}_{(0, \infty)}$ plus additional data $\varphi_{\mathcal{P}_{\eta}}$ and $\iota_{r}$ from [SW20, Definition 23.5.1] that we do not need to reference right now. The admissible locus is cut out by the condition that the Newton point $\nu_{\mathcal{P}_{\eta}}$ and the Kottwitz point $\kappa_{\mathcal{P}_{\eta}}$ are both identically zero [SW20, Theorem 22.6.2].

Definition 4.4.2. For a basic $b \in B(G)$, denote by $\operatorname{Gr}_{G, I}^{\mathrm{tw}, b}$ the subspace where $\nu_{\mathcal{P}_{\eta}}=\nu(b)$ and $\kappa_{\mathcal{P}_{\eta}}=\kappa(b)$. This is an open subspace, and when $b=1_{G}$ this recovers the admissible locus, i.e., $\operatorname{Gr}_{G, I}^{\mathrm{tw}, 1_{G}}=\operatorname{Gr}_{G, I}^{\mathrm{tw}, a} \subset \operatorname{Gr}_{G, I}^{\mathrm{tw}}$.

Example 4.4.3. If $b \in B(G)$ is basic, then there is a pure inner twist $G_{b}$ (sometimes denoted $J_{b}$ in the literature) and a canonical isomorphism

$$
\begin{equation*}
\operatorname{tr}_{b}: B(G) \xrightarrow{\sim} B\left(G_{b}\right) \tag{4.4}
\end{equation*}
$$

sending $b \in B(G)$ to $1_{G_{b}} \in B\left(G_{b}\right)$. There is also a compatible isomorphism $\operatorname{Gr}_{G, I}^{\mathrm{tw}} \cong \operatorname{Gr}_{G_{b}, I}^{\mathrm{tw}}$ as in [FS21, $\S$ III.4.1], which takes $\operatorname{Gr}_{G, I}^{\mathrm{tw}, b}$ to $\operatorname{Gr}_{G_{b}, I}^{\mathrm{tw}, a}$. So we could have formulated the subspaces $\operatorname{Gr}_{G, I}^{\mathrm{tw}, b}$ as admissible loci for pure inner twists $G_{b}$. However, we prefer to keep the distinction, for psychological reasons if nothing else.

Let $\iota: B(H) \rightarrow B(G)$ be the map induced by the inclusion $\iota: H \hookrightarrow G$. The induced map $\iota: \operatorname{Gr}_{H, I}^{\mathrm{tw}} \hookrightarrow \operatorname{Gr}_{G, I}^{\mathrm{tw}}$ is also a closed embedding (by the proof of [SW20, Lemma 19.1.5]), etc.

Remark 4.4.4. Since $X_{*}\left(T_{E^{s}}^{\sigma}\right)_{\mathbf{Q}} \subset X_{*}\left(T_{E^{s}}\right)_{\mathbf{Q}}$, the subset $\iota^{-1}\left(1_{G}\right) \subset B(H)$ consists of basic elements. For each $b^{\prime} \in \iota^{-1}\left(1_{G}\right)$, there is an embedding

$$
\iota \iota_{b^{\prime}}: H_{b^{\prime}} \hookrightarrow G_{\iota\left(b^{\prime}\right)}=G .
$$

As a variant of [FS21, Proposition III.4.2], this induces an embedding $\operatorname{Gr}_{H_{b^{\prime}}, I}^{\mathrm{tw}} \hookrightarrow \mathrm{Gr}_{G, I}^{\mathrm{tw}}$, identifying $\mathrm{Gr}_{H_{b^{\prime}, I}}^{\mathrm{tw}, a}$ with $\mathrm{Gr}_{H, I}^{\mathrm{tw}, b^{\prime}}$ as sub-v-sheaves of $\mathrm{Gr}_{G, I}^{\mathrm{tw}}$.

Lemma 4.4.5. We have

$$
\operatorname{Gr}_{G, I}^{\mathrm{tw}, a} \cap \mathrm{Gr}_{H, I}^{\mathrm{tw}}=\coprod_{b^{\prime} \in \iota^{-1}\left(1_{G}\right)} \operatorname{Gr}_{H, I}^{\mathrm{tw}, b^{\prime}}
$$

as subdiamonds of $\mathrm{Gr}_{G, I}^{\mathrm{tw}}$.
Proof. In Corollary 4.1.4 we have seen that $\operatorname{Fix}\left(\sigma, \operatorname{Gr}_{G, I}^{\mathrm{tw}}\right)=\mathrm{Gr}_{H, I}^{\mathrm{tw}}$ (with the obvious embedding). The admissible locus $\operatorname{Gr}_{G, I}^{\mathrm{tw}, a} \subset \operatorname{Gr}_{G, I}^{\mathrm{tw}}$ is cut out by the condition that $\nu\left(\mathcal{P}_{\eta}\right)=0$ and $\kappa\left(\mathcal{P}_{\eta}\right)=0$. Hence $\operatorname{Fix}\left(\sigma, \operatorname{Gr}_{G, I}^{\mathrm{tw}, a}\right)$ is the pullback of the simultaneous vanishing loci of the Newton and Kottwitz maps from $\mathrm{Gr}_{G, I}^{\mathrm{tw}}$ to $\mathrm{Gr}_{H, I}^{\mathrm{tw}}$, which is precisely the expression on the RHS.
4.4.2. Fixed points of moduli of local shtukas. We now recall more about the structure of $\operatorname{Sht}_{(G, b, I), K}$ in terms of the Grothendieck-Messing period map. According to [SW20, Corollary 23.4.2], Gr ${ }_{G, I}^{\mathrm{tw}, a}$ carries a

For basic $b^{\prime} \in B(G)$, note that $\mathrm{Gr}_{G, I}^{\mathrm{tw}, b^{\prime}}$ carries a $G_{b}^{\prime}(E)$-torsor that we denote $\mathbb{P}_{\eta}^{G, b^{\prime}}$, for example using the pure inner twisting procedure from [FS21, Proposition III.4.2] to reduce to the case where $b^{\prime}=1_{G}$ where it is $\mathbb{P}_{\eta}^{G}$.

Definition 4.4.6. Let $b^{\prime} \in B(G)$ be basic and $G_{b^{\prime}}$ the corresponding inner twist of $G$. For a compact open subgroup $K \subset G_{b^{\prime}}(E)$, we denote by $\operatorname{Sht}_{(G, b, I), K}^{b^{\prime}} \rightarrow \operatorname{Gr}_{G, I}^{\mathrm{tw}, b^{\prime}}$ the étale cover parametrizing $K$-lattices in $\mathbb{P}_{\eta}^{G}$. Note that $G_{b}(E)$ acts on $\operatorname{Sht}_{(G, b, I), K}^{b^{\prime}}$ by change of framing.

In fact, the pure inner twisting procedure of [FS21, Proposition III.4.2] gives a $G_{b}(E)$-equivariant isomorphism between $\operatorname{Sht}_{(G, b, I), K}^{b^{\prime}}$ and $\operatorname{Sht}_{\left(G_{\left.b^{\prime}, b^{\prime \prime}, I\right), K}\right.}$ for $b^{\prime \prime} \in B(G)$ such that the inner twist of $G_{b^{\prime}}$ corresponding to $b^{\prime \prime}$ is isomorphic to $G_{b}$, so it was unnecessary to introduce this new notation. However, we like to use it to distinguish what arises naturally from calculations.

For $b^{\prime} \in \iota^{-1}\left(1_{G}\right) \subset B(H)$, write $\iota_{b^{\prime}}^{*} K \subset H_{b^{\prime}}(E)$ for the pre-image of $K$ under the map $\iota_{b^{\prime}}: H_{b^{\prime}} \hookrightarrow G$ from Remark 4.4.4. We abbreviate $\iota^{*} K=\iota_{1_{H}}^{*} K=K^{\sigma} \subset H(E)$.
Proposition 4.4.7. Suppose $K \subset G(E)$ is a pro-p, $\Sigma$-stable open compact subgroup. Then we have

$$
\operatorname{Fix}\left(\sigma, \operatorname{Sht}_{\left(G, 1_{G}, I\right), K}\right)=\coprod_{b^{\prime} \in \iota^{-1}\left(1_{G}\right)} \operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota_{b^{\prime}}^{*} K}^{b^{\prime}}
$$

as sub-v-sheaves of $\operatorname{Sht}_{\left(G, 1_{G}, I\right), K}$ (with embedding on the RHS induced by $\iota_{b^{\prime}}$ of Remark 4.4.4). In particular, $\operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota^{*} K}$ is an open-closed subdiamond of $\operatorname{Fix}\left(\sigma, \operatorname{Sht}_{\left(G, 1_{G}, I\right), K}\right)$.

Remark 4.4.8. As explained in Definition 4.4.6, the term $\operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota_{b^{\prime}}}^{b^{\prime}}$ is $H(E)$-equivariantly isomorphic to the local Shimura variety $\operatorname{Sht}_{\left(H_{b^{\prime}}, b, I\right), \iota_{b^{\prime}}^{*} K}$ where $b \in B\left(H_{b^{\prime}}\right)$ is such that the inner twist $\left(H_{b^{\prime}}\right)_{b}$ is isomorphic to $H$. Only the assertion that $\operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota^{*} K}$ is an open-closed subdiamond of $\operatorname{Fix}\left(\sigma, \operatorname{Sht}_{\left(G, 1_{G}, I\right), K}\right)$, will be needed in future sections.

Proof. We compute using the Grothendieck-Messing period map. In view of Lemma 4.4.5, it suffices to show that for all $x \in \operatorname{Gr}_{H, I}^{\mathrm{tw}, b^{\prime}}$, the inclusion $\operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota_{b^{\prime}}^{*} K}^{b^{\prime}} \rightarrow \operatorname{Sht}_{\left(G, 1_{G}, I\right), K}$ sends $\left(\pi_{\mathrm{GM}}^{H}\right)^{-1}(x)$ isomorphically to $\operatorname{Fix}\left(\sigma,\left(\pi_{\mathrm{GM}}^{G}\right)^{-1}(x)\right)$. By pure inner twisting procedure, as explained in Remark 4.4.4 and Remark 4.4.8. we may reduce this statement to the case where $b^{\prime}=1$. The $G(E)$-torsor $\mathbb{P}_{\eta}^{G}$ corresponding to $x$ has an $H$-structure $\mathbb{P}_{\eta}^{H}$ since $x$ lies in the image of $\pi_{\mathrm{GM}}^{H}$, and $\left(\pi_{\mathrm{GM}}^{H}\right)^{-1}(x)$ parametrizes $\iota^{*} K$-lattices in $\mathbb{P}_{\eta}^{H}$. The action of $H(E)$ on a fixed $\iota^{*} K$-lattice $L_{0}$ induces an isomorphism $\left(\pi_{\mathrm{GM}}^{H}\right)^{-1}(x) \cong H(E) / \iota^{*} K$.

On the other hand, $\operatorname{Fix}\left(\sigma,\left(\pi_{\mathrm{GM}}^{G}\right)^{-1}(x)\right)$ parametrizes $K$-lattices in $\mathbb{P}_{\eta}^{G}$ which are stable under $\Sigma$. As $\mathbb{P}_{\eta}^{G} \cong$ $\mathbb{P}_{\eta}^{H} \times{ }^{H(E)} G(E)$, the action of $G(E)$ on $L_{0}$ induces an isomorphism $\operatorname{Fix}\left(\sigma,\left(\pi_{\mathrm{GM}}^{G}\right)^{-1}(x)\right) \cong \operatorname{Fix}(\sigma, G(E) / K)$, with $\sigma$ acting in the natural way. Hence it suffices to see that

$$
\begin{equation*}
H(E) / K^{\sigma} \xrightarrow{\sim}(G(E) / K)^{\sigma} . \tag{4.5}
\end{equation*}
$$

The long exact sequence of non-abelian cohomology of $\Sigma$ reads

$$
K^{\sigma} \hookrightarrow G(E)^{\sigma} \rightarrow(G(E) / K)^{\sigma} \rightarrow \mathrm{H}^{1}(\Sigma ; K) \rightarrow \mathrm{H}^{1}(\Sigma ; G(E))
$$

Since $K$ is pro- $p$ and $\Sigma$ has order $\ell \neq p$, we have $\mathrm{H}^{1}(\Sigma ; K)=0$. This shows 4.5), completing the proof.

## 5. Parity sheaf theory on $p$-adic affine Grassmannians

The theory of parity sheaves, originating in work of Juteau-Mautner-Williamson JMW14, has driven many recent developments in geometric representation theory: see AR15, AR16, MR18, AMRW19, Wil18, for a sampling of applications. Parity sheaves are defined somewhat similarly to perverse sheaves, but with parity conditions instead of inequalities on cohomological degrees.

In this section we develop a theory of relative parity sheaves on affine Grassmannians arising in p-adic geometry. The usage of the adjective "relative" is in the same sense as "relative perversity" of Hansen-Scholze [HS23]: it means parity along the geometric fibers of a morphism. In practice the morphism is the projection
of a Beilinson-Drinfeld type affine Grassmannian to the base. Leslie-Lonergan [L21] introduced the "Tateparity sheaves" as the analogue of parity sheaves in Tate categories, and we also develop a theory of "relative Tate-parity sheaves" on families of affine Grassmannians.

The main results of the structure theory of relative (Tate-)parity sheaves include the calculation of Ext groups, the vanishing of maps between incongruous objects, the Krull-Schmidt property, the rigidity of indecomposable objects, and the existence of relative (Tate-)parity sheaves associated to each stratum. Some of the difficulties are similar to those present in the theory of perverse sheaves on $p$-adic affine Grassmannians: the lack of a definitive dimension theory for adic spaces, and the failure of constructibility for the sheaves of interest. There are also some new technical issues, coming from the fact that the Ext-vanishing properties underlying the structure theory of parity sheaves have an "absolute" nature, which is in tension with the "relative" nature of our definitions. The theory of ULA sheaves developed in [FS21 ultimately helps us to overcome these difficulties.

We now give an overview of the contents of this section. In 5.1 we define relative parity complexes, etc. on $\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}}$ for a small v-stack $S$ over $\operatorname{Div}_{X}^{1}$ and establish their structure theory (mostly for the case where $S$ is strictly totally disconnected). In $\$ 5.2$ we introduce a "small" version of the Tate category for $\mathrm{Gr}_{G, S / \mathrm{Div}_{X}^{1}}$, the adjective "small" referring to that the sheaves are required to have strong finiteness properties, and a "small" version of Smith-Treumann localization. In $\$ 5.3$ we define relative Tate-parity complexes, etc. on $\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}}$ and establish their structure theory. In $\$ 5.4$ we define "even maps" and prove that they preserve relative parity, and next in $\$ 5.5$ we apply this to certain Demazure resolutions in order to show that relative parity sheaves exist for all strata, and that relative parity is preserved by convolution. In 85.6 we study the interaction of relative parity sheaves with modular reduction $\mathbb{F}$ and the operation $\mathbb{T}$. This is used in 85.7 to define the "lifting functor" à la Leslie-Lonergan, which will constitute a key step in the construction of the Brauer functor.
5.1. Relative parity sheaves. Let $S$ be a small v-stack with a map $S \rightarrow \operatorname{Div}_{X}^{1}$. Then we may form $\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}}:=\operatorname{Gr}_{G, \operatorname{Div}_{X}^{1}} \times \operatorname{Div}_{X}^{1} S$ and $\mathcal{H} \mathrm{ck}_{G, S / \operatorname{Div}_{X}^{1}}:=\mathcal{H}^{2} \mathrm{ck}_{G, \operatorname{Div}_{X}^{1}} \times{ }_{\operatorname{Div}_{X}^{1}} S$ as in [FS21, §VI].
5.1.1. Schubert stratification. Suppose $S \in$ Perf is strictly totally disconnected. Then [FS21, VI.2] applies and we have a presentation

$$
\mathcal{H}^{c k_{G, S /} \operatorname{Div}_{X}^{1}}=\underset{\mu \in \widehat{X_{*}(T)^{+}}}{ } \lim _{G, S / \operatorname{Div}_{X}^{1}, \leq \mu}
$$

where $T$ is a split maximal torus in $G_{E^{s}}$; here $\mathcal{H}^{c_{G, S / D i v}^{X}}{ }^{1}, \leq \mu$ is the subfunctor of $\mathcal{H} \mathrm{ck}_{G, S / \operatorname{Div}_{X}^{1}}$ parametrizing modifications which are given by some $\mu^{\prime} \leq \mu$ at each geometric point of $S$. The open subfunctor $\mathcal{H}^{\mathrm{ck}_{G, S /} \operatorname{Div}_{X}^{1}, \mu} \not{ } \hookrightarrow \mathcal{H}_{\mathrm{ck}_{G, S /} \operatorname{Div}_{X}^{1}, \leq \mu}$ is defined as the complement of $\mathcal{H} \mathrm{ck}_{G, S / \operatorname{Div}_{X}^{1}, \leq \mu^{\prime}}$ for $\mu^{\prime}<\mu$.

The pullback of $\mathcal{H} \mathrm{ck}_{G, S / \operatorname{Div}_{X}^{1}, \leq \mu}$ (resp. $\mathcal{H} \mathrm{ck}_{G, S / \operatorname{Div}_{X}^{1}, \mu}$ ) to $\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}}$ is denoted $\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}, \leq \mu}$ (resp. $\left.\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}, \mu}\right)$. Let $L_{S / \operatorname{Div}_{X}^{1}}^{+} G:=L_{\operatorname{Div}_{X}^{1}}^{+} G \times_{\operatorname{Div}_{X}^{1}} S$. Then $L_{S / \operatorname{Div}_{X}^{1}}^{+} G$ acts on $\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}}$ by left translation, and the orbits are the $\operatorname{Gr}_{G, S / \operatorname{Div}_{x}^{1}, \mu}$.

We denote by $i_{\mu}$ the locally closed embedding $i_{\mu}: \mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}, \mu} \hookrightarrow \mathrm{Gr}_{G, S / \mathrm{Div}_{X}^{1}}$. By [FS21, Proposition VI.2.4], $\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}, \mu}$ has the structure of a fibration over the diamond of the (opposite) partial flag variety $\left(P_{\mu}^{-}\right)_{S}^{\ominus}$, with the fibers being iterated extensions of $(\operatorname{Lie} G)_{\mu \leq m}^{\ominus}\{m\}$ where $(\operatorname{Lie} G)_{\mu \leq m}$ is the subspace on which $\mathbf{G}_{m}$ acts with weights $\leq m$ via the adjoint action composed with $\mu$. (Here $\{m\}$ is a "Breuil-Kisin twist".)

Lemma 5.1.1. For the projection $\pi: \operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}, \mu} \rightarrow S$, each $\mathrm{R}^{n} \pi_{*} \Lambda$ has $\Lambda$-free geometric stalks and vanishes if $n$ is odd.

Proof. Both $\left(P_{\mu}^{-}\right)^{\diamond}$ and $(\operatorname{Lie} G)_{\mu \leq m}^{\diamond}$ have the property that their cohomology with constant coefficients is supported in even degrees. The preceding description shows that $\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}, \mu}$ is an iterated fibration over $\left(P_{\mu}^{-}\right)_{S}^{\diamond}$ with fibers of the form $(\operatorname{Lie} G)_{\mu \leq m}^{\diamond}$ (note that the Breuil-Kisin twist is trivializable over geometric points), so the result follows from the Serre spectral sequence, which is forced to degenerate by the evenness.
5.1.2. Categories of sheaves. We will take coefficients in a ring $\Lambda$ which is a complete local PID over $\mathbf{Z}_{\ell}$, i.e., a field of characteristic $\ell$ or a complete DVR with residue characteristic $\ell$. In our applications of interest, $\Lambda$ will be either $k$ or $\mathbb{O}:=W(k)$.

Definition 5.1.2. We define $D_{(L+G)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ to be the full subcategory of $D_{\text {êt }}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ spanned by the image of $D_{\text {ett }}^{\mathrm{ULA}}\left(\mathcal{H c k}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ under $*$-pullback.

Remark 5.1.3 (Stability under six operations). As a consequence of [FS21, Corollary VI.6.6], the category $D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ is stable under the operations of Verdier duality, $-\stackrel{\mathrm{\otimes}}{\otimes_{\Lambda}}-, \mathcal{R} \mathcal{H o m}_{\Lambda}(-,-)$, $i_{!} i^{*}, \mathrm{R} i_{*} i^{*}, i_{!} i^{!}, \mathrm{R} i_{*} i^{!}$where $i=i_{\mu}$ is the inclusion of any stratum. (The analogous statement does not hold in the "multiple legs" situation, unless the map from $S$ factors through the locus where the legs are disjoint.)

Recall that an additive category is called Krull-Schmidt if each object is a finite direct sum of indecomposable objects with local endomorphism rings (in particular, this implies that an object is indecomposable if and only if its endomorphism ring is local). We will show that $D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ is Krull-Schmidt.

Lemma 5.1.4. All objects of $D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ admit a finite filtration by objects of the form $i_{\mu!} \Lambda$, and also a finite filtration by objects of the form $\mathrm{R} i_{\mu *} \Lambda$.

Proof. This follows immediately from [FS21, Proposition VI.6.5].
Lemma 5.1.5. For any object $\mathcal{K} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}, \operatorname{End}(\mathcal{K})$ is finitely generated as a $\Lambda$-module.
Proof. Applying Lemma 5.1.4, it suffices to show that for each $\mu \in X_{*}(T)^{+}$,
$\operatorname{Hom}\left(i_{\mu!} \Lambda, \operatorname{R} i_{\mu^{\prime} *} \Lambda\right) \cong \operatorname{Hom}\left(i_{\mu^{\prime}}^{*} i_{\mu!} \Lambda, \Lambda\right)$ is finitely generated as a $\Lambda$-module.
If $\mu \neq \mu^{\prime}$, then $i_{\mu^{\prime}}^{*} i_{\mu!} \Lambda=0$. If $\mu^{\prime}=\mu$, then $i_{\mu^{\prime}}^{*} i_{\mu!} \Lambda \cong \Lambda$, so that $\operatorname{Hom}\left(i_{\mu^{\prime}}^{*} i_{\mu!} \Lambda, \Lambda\right) \cong \Lambda$.
Lemma 5.1.6. The category $D_{(L+G)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ is Krull-Schmidt.
Proof. The usual t-structure on the category $D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \mathrm{Div}_{X}^{1}} ; \Lambda\right)^{\text {bd }}$ is bounded. Therefore, it is Karoubian (i.e., every idempotent splits) by [LC07, Theorem]. By CYZ08, Theorem A.1], a Karoubian category such that $\operatorname{End}(\mathcal{K})$ is semiperfect (cf. Lam01, Chapter 8] for a reference on semiperfect rings) for every $\mathcal{K}$ is KrullSchmidt. It therefore suffices to show that $\operatorname{End}(\mathcal{K})$ is semiperfect for every $\mathcal{K} \in D_{(L+G)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$. For this we note that any finite $\Lambda$-algebra is semiperfect, and we showed in Lemma 5.1.5 that $\operatorname{End}(\mathcal{K})$ is a finite $\Lambda$-module.
5.1.3. Relative parity complexes. A pariversity on $\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}}$ is a function $\dagger$ from $X_{*}(T)^{+}$, thought of as the set of strata on the geometric fibers over $S$, to $\mathbf{Z} / 2 \mathbf{Z}$.

Example 5.1.7 (Dimension pariversity). In this section we fix $\dagger_{\text {to }}$ be the "dimension pariversity" $\dagger_{G}$, defined by

$$
\dagger_{G}(\lambda):=\langle 2 \rho, \lambda\rangle \quad(\bmod 2) \in \mathbf{Z} / 2 \mathbf{Z}
$$

where $2 \rho$ is the sum of the positive roots of $G$.
The definition below is a "relative to $S$ " (in a sense parallel to the notion of relative perversity in FS21, §VI.7]) version of the definition of parity sheaves in [JMW14, Definition 2.4].
Definition 5.1.8 (Parity complexes). Let $S$ be a small v-stack. For a geometric point $\bar{s}=\operatorname{Spa}\left(C, C^{+}\right) \rightarrow S$ and $\mathcal{K} \in D_{(L+G)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\text {bd }}$, we denote by $\left.\mathcal{K}\right|_{\bar{s}}$ the $*$-restriction of $\mathcal{K}$ along $\mathrm{Gr}_{G, \bar{s} / \operatorname{Div}_{X}^{1}} \rightarrow \mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}}$. For each $\mu \in X_{*}(T)^{+}$we let $i_{\mu}: \operatorname{Gr}_{G, \bar{s} / \operatorname{Div}_{X}^{1}, \mu} \hookrightarrow \operatorname{Gr}_{G, \bar{s} / \operatorname{Div}_{X}^{1}}$ be the locally closed embedding of the corresponding stratum.
(1) For $? \in\{*,!\}$, we say $\mathcal{K} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\text {bd }}$ is relative ?-even if for all geometric points $\bar{s} \rightarrow S$ and all $\mu \in X_{*}(T)^{+}$and all $n \in \mathbf{Z}$, the cohomology sheaf $\mathcal{H}^{n}\left(i_{\mu}^{?}\left(\left.\mathcal{K}\right|_{\bar{s}}\right)\right)$ is constant and $\Lambda$-free, and vanishes for $n \not \equiv \dagger(\mu)(\bmod 2)$.
(2) For $? \in\{*,!\}$, we say that $\mathcal{K} \in D_{(L+G)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\text {bd }}$ is relative ?-odd if $\mathcal{K}[1]$ is relative ?-even.
(3) For ? $\in\{*,!\}$, we say that $\mathcal{K} \in D_{(L+G)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\text {bd }}$ is relative ?-parity if $\mathcal{K}$ is either relative ?-even or relative ?-odd.
(4) We say $\mathcal{K} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\text {bd }}$ is a relative even complex if $\mathcal{K}$ is relative $*$-even and relative !-even. We say that $\mathcal{K} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ is a relative odd complex if $\mathcal{K}[1]$ is even.
(5) We say $\mathcal{K} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ is a relative parity complex if it is isomorphic to a finite direct sum of relative even and relative odd complexes. The full subcategory of $D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ spanned by relative parity complexes is denoted $\operatorname{Par}{ }^{U L A}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)$.
The following result is part of [FS21, Corollary VI.6.6], but we state it for emphasis and as an opportunity to spell out the proof.

Lemma 5.1.9 ([FS21]). Let $f: S^{\prime} \rightarrow S$ be a map of small v-stacks over $\operatorname{Div}_{X}^{1}$ and $i_{\mu}: \operatorname{Gr}_{G, S / \operatorname{Div}}, \mu, \mu$ $\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}}$ be the locally closed immersion of a Schubert cell. Consider the diagram

where all squares are Cartesian. Then we have a natural isomorphism $f_{\mu}^{*}\left(i_{\mu}\right)^{!} \cong\left(i_{\mu}^{\prime}\right)!\widetilde{f}^{*}$ of functors $D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}} \rightarrow D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S^{\prime} / \operatorname{Div}_{X}^{1}, \mu} ; \Lambda\right)^{\mathrm{bd}}$.
Proof. We abbreviate $\mathbb{D}_{/ S}$ (resp. $\mathbb{D}_{/ S^{\prime}}$ ) for the relative Verdier duality over $S$ (resp. $S^{\prime}$ ). By [FS21, Proposition IV.2.15], relative Verdier duality is compatible with base change, meaning there are natural isomorphisms

$$
\begin{equation*}
f_{\mu}^{*} \mathbb{D}_{/ S} \xrightarrow{\sim} \mathbb{D} / S^{\prime} f_{\mu}^{*} \quad \text { and } \quad \widetilde{f}^{*} \mathbb{D} / S \xrightarrow{\sim} \mathbb{D} / S^{\prime} \widetilde{f}^{*} . \tag{5.1}
\end{equation*}
$$

Using also that $i_{\mu}^{!} \cong \mathbb{D}_{/ S} i_{\mu}^{*} \mathbb{D}_{/ S}$ and $\left(i_{\mu}^{\prime}\right)^{!} \cong \mathbb{D}_{/ S^{\prime}}\left(i_{\mu}^{\prime}\right)^{*} \mathbb{D}_{/ S^{\prime}}$ on ULA objects (because relative Verdier duality is involutive on ULA objects [FS21, Corollary IV.2.25]), we have natural isomorphisms

$$
f_{\mu}^{*} i_{\mu}^{!} \cong f_{\mu}^{*} \mathbb{D}_{/ S} i_{\mu}^{*} \mathbb{D}_{/ S} \stackrel{\sqrt[5.1]]{\approx}}{\approx} \mathbb{D}_{/ S^{\prime}} f_{\mu}^{*} i_{\mu}^{*} \mathbb{D}_{/ S} \cong \mathbb{D}_{/ S^{\prime}}\left(i_{\mu}^{\prime}\right)^{*} \widetilde{f}^{*} \mathbb{D}_{/ S} \stackrel{5.1}{\cong} \mathbb{D}_{/ S^{\prime}}\left(i_{\mu}^{\prime}\right)^{*} \mathbb{D}_{/ S^{\prime}} \widetilde{f}^{*} \cong\left(i_{\mu}^{\prime}\right)^{!} \widetilde{f}^{*} .
$$

5.1.4. Structure theory for strictly totally disconnected $S$. Here we prove several structural results about $\operatorname{Par}{ }^{\text {ULA }}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)$, parallel to JMW14, §2], under the assumption that $S$ is strictly totally disconnected. In particular, we have the stratification of $\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}}$ by $\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}, \mu}$, ranging over $\mu \in X_{*}(T)^{+}$, and we let $i_{\mu}$ be the locally closed embedding $\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}, \mu} \hookrightarrow \operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}}$. Below all Hom and Ext groups are taken in the category $D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\text {bd }}$, which we omit for ease of notation.

Lemma 5.1.9 implies the following connection between relative parity as in Definition 5.1.8, and an "absolute" notion of parity.

Corollary 5.1.10. Let $\mathcal{K} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$. For $? \in\{*,!\}$, if $\mathcal{K}$ is relative ?-even then for all $\mu \in X_{*}(T)^{+}$and all $n \in \mathbf{Z}$, the cohomology sheaf $\mathcal{H}^{n}\left(i_{\mu}^{?}(\mathcal{K})\right)$ is constant and $\Lambda$-free, and vanishes for $n \not \equiv \dagger(\mu)$ $(\bmod 2)$.
Proof. The constancy is by definition of $D_{\left(L^{+G}\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\text {bd }}$, and the $\Lambda$-freeness of $*$-restrictions can be checked on stalks so follows from the definition of relative ?-even, using Lemma 5.1.9. The fact that $\mathcal{H}^{n}\left(i_{\mu}^{*}(\mathcal{K})\right)$ vanishes for $n \not \equiv \dagger(\mu)(\bmod 2)$ follows immediately from the definition of relative ?-even, while the fact that $\mathcal{H}^{n}\left(i_{\mu}^{!}(\mathcal{K})\right)$ vanishes for $n \not \equiv \dagger(\mu)(\bmod 2)$ can be checked after base change along geometric points $\bar{s}=\operatorname{Spa}\left(C, C^{+}\right) \rightarrow S$, where it follows from the definition of relative ?-even using Lemma 5.1.9.
Lemma 5.1.11. Assume $S$ is strictly totally disconnected. If $\mathcal{F} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ is relative *-parity and $\mathcal{G} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\text {bd }}$ is relative !-parity, then we have a (non-canonical) isomorphism of $\Lambda$-modules

$$
\operatorname{Ext} \cdot(\mathcal{F}, \mathcal{G}) \cong \bigoplus_{\mu \in X_{*}(T)^{+}} \operatorname{Ext}\left(i_{\mu}^{*} \mathcal{F}, i_{\mu}^{!} \mathcal{G}\right)
$$

and both sides are free over $\Lambda$.

Proof. The argument is similar to that for JMW14, Proposition 2.6], but we have to address some issues related to the discrepancy between our relative situation and the "absolute" situation of JMW14. Since the statement is compatible with finite direct sums in $\mathcal{F}$ and $\mathcal{G}$, and $D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\text {bd }}$ is Krull-Schmidt by Lemma 5.1.6, we may assume that $\mathcal{F}$ and $\mathcal{G}$ are indecomposable. Since the statement is compatible with shifts, we may further assume that $\mathcal{F}$ is relative $*$-even and $\mathcal{G}$ is relative !-even.

We will show by induction, on the number $N$ of strata where $\mathcal{F}$ is supported, that (i) $\operatorname{Ext}{ }^{\bullet}(\mathcal{F}, \mathcal{G})$ is $\Lambda$-free and vanishes in odd degrees and (ii) satisfies the decomposition asserted in the Lemma. If $N=1$, then $\mathcal{F} \cong i_{\mu!} i_{\mu}^{*} \mathcal{F}$ for some $\mu \in X_{*}(T)^{+}$, and we have

$$
\operatorname{Ext}^{\bullet}(\mathcal{F}, \mathcal{G}) \cong \operatorname{Ext}^{\bullet}\left(i_{\mu!} i_{\mu}^{*} \mathcal{F}, \mathcal{G}\right) \cong \operatorname{Ext}^{\bullet}\left(i_{\mu}^{*} \mathcal{F}, i_{\mu}^{!} \mathcal{G}\right)
$$

This shows part (ii) of the inductive hypothesis. By Corollary 5.1.10, $i_{\mu}^{*} \mathcal{F}$ and $i_{\mu}^{!} \mathcal{G}$ are both constant complexes on $\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}}$ concentrated in even degrees. Then part (i) of the induction hypothesis follows from Lemma 5.1.1 (using that $S$ is strictly totally disconnected).

If $N>1$, let $i$ be the inclusion of a closed stratum in the support of $\mathcal{F}$ and consider the excision sequence $j_{!} j^{*} \mathcal{F} \rightarrow \mathcal{F} \rightarrow i_{*} i^{*} \mathcal{F}$. Applying $\operatorname{Hom}(-, \mathcal{G})$, we get a long exact sequence

$$
\begin{equation*}
\ldots \rightarrow \operatorname{Ext}^{n}\left(i_{*} i^{*} \mathcal{F}, \mathcal{G}\right) \rightarrow \operatorname{Ext}^{n}(\mathcal{F}, \mathcal{G}) \rightarrow \operatorname{Ext}^{n}\left(j!j^{*} \mathcal{F}, \mathcal{G}\right) \rightarrow \ldots \tag{5.2}
\end{equation*}
$$

Rewriting $\operatorname{Ext}^{n}\left(i_{*} i^{*} \mathcal{F}, \mathcal{G}\right) \cong \operatorname{Ext}^{n}\left(i^{*} \mathcal{F}, i^{*} \mathcal{G}\right)$ and $\operatorname{Ext}^{n}\left(j!j^{*} \mathcal{F}, \mathcal{G}\right) \cong \operatorname{Ext}^{n}\left(j^{*} \mathcal{F}, j^{*} \mathcal{G}\right)$, the induction hypothesis applies to the flanking terms. In particular (i) implies that the long exact sequence (5.2) splits, and then (i) and (ii) for the flanking terms imply (i) and (ii) for $\operatorname{Ext}^{\bullet}(\mathcal{F}, \mathcal{G})$.

Corollary 5.1.12. Assume $S$ is strictly totally disconnected. If $\mathcal{F} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\text {bd }}$ is relative *-even and $\mathcal{G} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ is relative !-odd, then $\operatorname{Hom}(\mathcal{F}, \mathcal{G})=0$.
Lemma 5.1.13. Assume $S$ is strictly totally disconnected. Suppose $\mathcal{F}, \mathcal{G} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \mathrm{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ are indecomposable and either both relative even or both relative odd. If $i_{\mu}$ is the inclusion of a stratum which is open in the support of both $\mathcal{F}$ and $\mathcal{G}$, then the restriction map $\operatorname{Hom}(\mathcal{F}, \mathcal{G}) \rightarrow \operatorname{Hom}\left(i_{\mu}^{*} \mathcal{F}, i_{\mu}^{*} \mathcal{G}\right)$ is surjective.

Proof. By symmetry it suffices to treat the case where $\mathcal{F}, \mathcal{G}$ are both relative even. Let $i$ be in the inclusion of the complementary strata, so that we have an excision triangle of relative !-even complexes,

$$
i_{*}!!\mathcal{G} \rightarrow \mathcal{G} \rightarrow i_{\mu *} i_{\mu}^{*} \mathcal{G}
$$

Applying $\operatorname{Hom}(\mathcal{F},-)$, we obtain a long exact sequence

$$
\ldots \rightarrow \operatorname{Hom}(\mathcal{F}, \mathcal{G}) \rightarrow \operatorname{Hom}\left(i_{\mu}^{*} \mathcal{F}, i_{\mu}^{*} \mathcal{G}\right) \rightarrow \operatorname{Hom}\left(\mathcal{F}, i_{*} i^{!} \mathcal{G}[1]\right) \rightarrow \ldots
$$

and $\operatorname{Hom}\left(\mathcal{F}, i_{*} i^{!} \mathcal{G}[1]\right)=0$ by Corollary 5.1.12, because $\mathcal{G}[1]$ is relative !-odd.
Lemma 5.1.14. Assume $S$ is strictly totally disconnected. Let $\mathcal{F} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ be an indecomposable relative parity complex, and let $j: U \rightarrow \operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}}$ be an inclusion of a union of strata open in the support of $\mathcal{F}$. Then $j^{*} \mathcal{F}$ is either zero or indecomposable.

Proof. Since $D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\text {bd }}$ is Krull-Schmidt by Lemma 5.1.6. the indecomposability of $\mathcal{F}$ implies that $\operatorname{End}(\mathcal{F})$ is local. As a quotient of a local ring is local, Lemma 5.1.13 implies that $\operatorname{Hom}\left(j^{*} \mathcal{F}, j^{*} \mathcal{F}\right)$ is also local, so $j^{*} \mathcal{F}$ is either zero or indecomposable.

Proposition 5.1.15. Assume $S$ is strictly totally disconnected. Let $\mathcal{F} \in \operatorname{Par}^{\operatorname{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)$ be an indecomposable relative parity complex. Then $\mathcal{F}$ enjoys the following properties:
(1) $\mathcal{F}$ has support of the form $\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}, \leq \mu}$ for some $\mu \in X_{*}(T)^{+}$.
(2) The restriction $i_{\mu}^{*} \mathcal{F}$ to the open stratum $\operatorname{in} \operatorname{supp}(\mathcal{F})$ is a shifted $\Lambda$-free constant sheaf $\Lambda[d]$.
(3) Any indecomposable relative parity complex $\mathcal{G} \in \operatorname{Par}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)$ supported on $\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}, \leq \mu}$, such that $i_{\mu}^{*} \mathcal{G} \cong \Lambda[d]$ on $\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}, \mu}$, is isomorphic to $\mathcal{F}$.

Proof. (1) If $\operatorname{supp}(\mathcal{F})$ contains two disjoint open strata $U, U^{\prime}$ then applying Lemma 5.1.13 to each of $U$ and $U^{\prime}$ provides a non-local quotient of $\operatorname{End}(\mathcal{F})$. But since $\mathcal{F}$ is indecomposable, the Krull-Schmidt property (Lemma 5.1.6) implies that $\operatorname{End}(\mathcal{F})$ is local.
(2) Follows from Lemma 5.1.14
(3) Since $\mathcal{F}$ is assumed to be indecomposable, the Krull-Schmidt property (Lemma 5.1.6) implies that $\operatorname{End}(\mathcal{F})$ is a local ring. By assumption, there are isomorphisms $\alpha: i_{\mu}^{*} \mathcal{F} \rightarrow i_{\mu}^{*} \mathcal{G}$ and $\beta: i_{\mu}^{*} \mathcal{G} \rightarrow i_{\mu}^{*} \mathcal{F}$ which are mutual inverses. By Lemma 5.1.13 we can find lifts $\widetilde{\alpha}: \mathcal{F} \rightarrow \mathcal{G}$ and $\widetilde{\beta}: \mathcal{G} \rightarrow \mathcal{F}$ such that $\widetilde{\beta} \circ \widetilde{\alpha} \in \operatorname{End}(\mathcal{F})$ does not lie in the unique maximal ideal of $\operatorname{End}(\mathcal{F})$, hence is invertible. Similarly, $\widetilde{\alpha} \circ \widetilde{\beta} \in \operatorname{End}(\mathcal{G})$ is invertible. Therefore, $\widetilde{\alpha}$ and $\widetilde{\beta}$ are isomorphisms.

Definition 5.1.16 (Parity sheaves). Assume that $S$ is strictly totally disconnected. We say that $\mathcal{F} \in$ $\operatorname{Par}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)$ is a relative parity sheaf (with respect to $\dagger$ ) if it is an indecomposable relative parity complex (with respect to $\dagger$ ). Note that relative parity sheaves are not (necessarily) sheaves.

We write $\mathcal{F} \cong \mathcal{E}(\mu, \mathcal{L})$ if $\mathcal{F}$ has support $\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}, \leq \mu}$ and $i_{\mu}^{*} \mathcal{F} \cong \mathcal{L}$. Note that for any particular $\mu$, we are not guaranteed a priori that $\mathcal{E}(\mu, \mathcal{L})$ exists.
5.2. Small Smith-Treumann localization. We develop here a version of the Tate category and SmithTreumann localization which is "small" in the sense that it consists only of sheaves satisfying strong finiteness conditions. It is more similar to the formalism of [Tre19, RW22] but we note that our sheaves are still not "constructible" since the Schubert stratifications are not constructible in $p$-adic geometry (due to failure of quasicompactness). The structure theory of ULA sheaves (relative to $S$ ) on $\mathcal{H}^{\left(\mathrm{ck}_{G, S /} \operatorname{Div}_{X}^{1}\right.}$ from [FS21] is what makes this small version well behaved even in the absence of quasicompactness.
5.2.1. The small Tate category. Let $\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)^{\mathrm{bd}} \subset D_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right)^{\mathrm{bd}}$ be the full subcategory spanned by objects with finite tor-dimension over $\Lambda[\Sigma]$.

Definition 5.2.1. We define the small Tate category of $\mathrm{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}$ to be the Verdier quotient

$$
\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}}:=\frac{D_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)^{\mathrm{bd}}}{\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)^{\mathrm{bd}}}
$$

and the small Tate category of $\mathcal{H} \mathrm{ck}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}$ to be

$$
\operatorname{Perf}^{\mathrm{ULA}}\left(\mathcal{H}^{\mathrm{Lc}}{ }_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}}:=\frac{D_{\mathrm{et}}^{\mathrm{ULA}}\left(\mathcal{H c k}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)^{\mathrm{bd}}}{\operatorname{Perf}^{\mathrm{ULA}}\left(\mathcal{H c k}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)^{\mathrm{bd}}}
$$

We make analogous definitions for $\mathrm{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}, \mu}$ and $\mathrm{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}, \leq \mu}$, etc.
Parallel to Lemma 3.2 .4 , we give an alternate characterization of $\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)^{\mathrm{bd}}$; note that this one applies without assuming that $\Lambda=k$ is a field.
Lemma 5.2.2. The subcategory $\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)^{\mathrm{bd}} \subset D_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)^{\mathrm{bd}}$ coincides with the full subcategory spanned by objects whose stalks at all geometric points are perfect complexes over $\Lambda[\Sigma]$.
Proof. By [FS21, Proposition VI.6.5] all geometric stalks of all objects of $\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{\left.H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I} ; \Lambda[\Sigma]\right)^{\mathrm{bd}} .}\right.$ are pseudocoherent, and have finite tor-amplitude by [Sta20, Tag 0DJJ]. Pseudo-coherent plus finite toramplitude implies perfect by [Sta20, Tag 0656]; this shows one containment.

For the other containment, we must show that if $\mathcal{K} \in D_{\left(L^{+} H\right)}^{U L A}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)^{\text {bd }}$ has all geometric stalks being perfect complexes over $\Lambda[\Sigma]$, then $\mathcal{K}$ finite tor-amplitude. By [Sta20, Tag 0DJJ], it suffices to exhibit a uniform bound on the tor-amplitude of the stalks. The rest of the proof is as for Lemma 3.2.4, except we use that for a perfect complex over $\Lambda[\Sigma]$, the properties of being flat and projective coincide by Sta20, Tag 051E].

Remark 5.2.3 (Comparison to the large Tate category). The tautological fully faithful embedding

$$
D_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)^{\mathrm{bd}} \hookrightarrow D_{\text {êt }}^{b}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)
$$

carries $\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)^{\text {bd }}$ into $\operatorname{Flat}^{b}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)$ and so induces a functor

$$
\begin{equation*}
\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}} \rightarrow \operatorname{Shv}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \mathcal{T}_{\Lambda}\right) \tag{5.3}
\end{equation*}
$$

which is conservative; similarly for the equivariant version.

Definition 5.2.4. We denote by

$$
\mathbb{T}^{*}: D_{(L+H)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)^{\mathrm{bd}} \rightarrow \operatorname{Perf}^{\mathrm{ULA}}\left(\mathcal{H}^{2} \mathrm{ck}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}}
$$

the tautological projection.
We denote by

$$
\epsilon^{*}: D_{(L+H)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right)^{\mathrm{bd}} \rightarrow D_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda[\Sigma]\right)^{\mathrm{bd}}
$$

the inflation via the augmentation $\Lambda[\Sigma] \rightarrow \Lambda$.
We write

$$
\mathbb{T}:=\mathbb{T}^{*} \varepsilon^{*}: D_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right)^{\mathrm{bd}} \rightarrow \operatorname{Perf}^{\mathrm{ULA}}\left(\mathcal{H}^{\left(c^{2}\right.}{ }_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}}
$$

These functors are compatible with the ones having the same notations in $\$ 3.2$, under (5.3). We use the same notation for the analogous operations for strata, Schubert varieties, and $\mathcal{H} \mathrm{ck}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}$, etc.
5.2.2. The small Psm operation. We now define the version of the "Smith operation" Psm from $\$ 3.6$ for small Tate categories. We assume the setup of $\mathbb{4} G$ has a $\Sigma$-action and $H:=H^{\sigma}$ is reductive, so that $\operatorname{Fix}\left(\sigma, \operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}\right)=\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}$ by Proposition 4.1.2.

Lemma 5.2.5. Let $\iota$ : $\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} \hookrightarrow \operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}$ be the inclusion of the $\Sigma$-fixed points. For any $\mathcal{F} \in D_{\text {ét }}^{U L A}\left(\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right)^{\mathrm{bd}}$, the restriction $\iota^{*} \mathcal{F} \in D_{\text {ét }}^{U L A}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right)^{\text {bd }}$ is ULA over $S$.

Proof. The condition can be checked v-locally on $S$ by [FS21, Proposition IV.2.5]. Therefore, we may assume that $G$ has a Borus $(B, T)$. Let $\left(B_{H}, T_{H}\right)=\left(B^{\sigma}, T^{\sigma}\right)$ be the corresponding Borus of $H$ (cf. Lemma 4.2.1). Recall the constant term functors CT from [FS21, §VI.3]. Applying (a variant of) [FS21, Proposition VI.6.4], it suffices to check that $\mathrm{CT}_{B_{H}}\left(i^{*} \mathcal{F}\right)$ is ULA over $S$. By proper base change applied to the commutative diagram

all of whose squares are Cartesian (thanks to Proposition 4.1.2 and Proposition 4.2.2), we have a natural isomorphism $\mathrm{CT}_{B_{H}}\left(\iota^{*} \mathcal{F}\right) \cong \iota^{*} \mathrm{CT}_{B}(\mathcal{F})$. By (a variant of) [FS21, Proposition VI.6.4], $\mathrm{CT}_{B}(\mathcal{F}) \in$ $D_{\text {êt }}^{\mathrm{ULA}}\left(\mathrm{Gr}_{T, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right)^{\mathrm{bd}}$ is ULA over $S$. Now $\iota: \mathrm{Gr}_{T_{H}, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} \hookrightarrow \operatorname{Gr}_{T, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}$ is an open embedding, hence $\ell$-cohomologically smooth, so $\iota^{*} \mathrm{CT}_{B}(\mathcal{F})$ is ULA over $S$ by [FS21, Proposition IV.2.13(i)].

Definition 5.2.6 (Small Smith operation). The (small) Smith operation is the functor

$$
\begin{equation*}
\operatorname{Psm}:=\mathbb{T}^{*} \circ \iota^{*}:\left(D_{(L+G)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right)^{\mathrm{bd}}\right)^{B \Sigma} \rightarrow \operatorname{Perf}_{(L+H)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}} \tag{5.4}
\end{equation*}
$$

which is well-defined by Lemma 5.2.5
The functor Psm has an equivariant version, which we also denote

$$
\operatorname{Psm}:\left(D_{\text {êt }}^{\mathrm{ULA}}\left(\mathcal{H} \mathrm{ck}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right)^{\mathrm{bd}}\right)^{B \Sigma} \rightarrow \operatorname{Perf}^{\mathrm{ULA}}\left(\mathcal{H} \mathrm{ck}_{H, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}}
$$

5.2.3. Compatibilities. We now establish some compatibility statements that could be remembered under the slogan, "the Smith operation commutes with all functors".

Notation 5.2.7. Below we let $Y, Y^{\prime}$ be spaces of the form $\mathrm{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}$, or the $m$-step convolution version thereof, or the twisted Grassmannian $\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}}^{\mathrm{tw}}$ or (closures of) strata thereof, and $f: Y \rightarrow Y^{\prime}$ be a map induced by a group homomorphism $G \rightarrow G^{\prime}$, or a convolution map. In all such cases, the small Tate categories of $Y^{\sigma}$ and $\left(Y^{\prime}\right)^{\sigma}$ are defined, because of Proposition 4.1.2 and Corollary 4.1.4. The Smith operation is also defined, and will be denoted

$$
\operatorname{Psm}: D_{?}^{\mathrm{ULA}}(Y ; \Lambda) \rightarrow \operatorname{Perf}_{?}^{\mathrm{ULA}}\left(Y^{\sigma} ; \mathcal{T}_{\Lambda}\right)
$$

where ? refers to the constructible or equivariant conditions.
Example 5.2.8. We allow $G^{\prime}$ to be the trivial group, in which case $\operatorname{Gr}_{G^{\prime}, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} \cong S$.

Let $f: Y \rightarrow Y^{\prime}$ be a $\Sigma$-equivariant morphism of the type in Notation 5.2.7. Let $f^{\sigma}: Y^{\sigma} \rightarrow\left(Y^{\prime}\right)^{\sigma}$ be the induced map of fixed points. It is clear that the pullback functor $\left(f^{\sigma}\right)^{*}: D_{?}^{\mathrm{ULA}}\left(\left(Y^{\prime}\right)^{\sigma} ; \Lambda\right)^{B \Sigma} \rightarrow$ $D_{?}^{\mathrm{ULA}}\left(Y^{\sigma} ; \Lambda\right)^{B \Sigma}$ preserves the perfect subcategories, hence descends to a functor

$$
\begin{equation*}
\left(f^{\sigma}\right)^{*}: \operatorname{Perf}_{?}^{\mathrm{ULA}}\left(\left(Y^{\prime}\right)^{\sigma} ; \mathcal{T}_{\Lambda}\right) \rightarrow \operatorname{Perf}_{?}^{\mathrm{ULA}}\left(Y^{\sigma} ; \mathcal{T}_{\Lambda}\right) \tag{5.5}
\end{equation*}
$$

We have the properties analogous to 3.4 in this situation. Applying relative Verdier duality to (5.5), we also get

$$
\begin{equation*}
\left(f^{\sigma}\right)^{!}: \operatorname{Perf}_{?}^{\mathrm{ULA}}\left(\left(Y^{\prime}\right)^{\sigma} ; \mathcal{T}_{\Lambda}\right) \rightarrow \operatorname{Perf}_{?}^{\mathrm{ULA}}\left(Y^{\sigma} ; \mathcal{T}_{\Lambda}\right) \tag{5.6}
\end{equation*}
$$

Below, when we say that diagrams "canonically commute", we mean that we construct explicit natural isomorphisms.

Lemma 5.2.9. Let $f: Y \rightarrow Y^{\prime}$ be a $\Sigma$-equivariant morphism of the type in Notation 5.2.7. The following diagrams canonically commute:

Proof. Evident from the definitions.
Let $f: Y \rightarrow Y^{\prime}$ be a $\sigma$-equivariant morphism of the type in Notation 5.2.7. For $f^{\sigma}: Y^{\sigma} \rightarrow\left(Y^{\prime}\right)^{\sigma}$ the induced map of fixed points, Lemma 3.4 .5 and FS21, Proposition VI.6.5] imply that $\mathrm{R} f_{!}^{\sigma}$ and $\mathrm{R} f_{*}^{\sigma}$ preserve the perfect subcategories, hence descend to

$$
\begin{aligned}
& \operatorname{R} f_{!}^{\sigma}: \operatorname{Perf}_{?}^{\mathrm{ULA}}\left(Y^{\sigma} ; \mathcal{T}_{\Lambda}\right) \rightarrow \operatorname{Perf}_{?}^{\mathrm{ULA}}\left(\left(Y^{\prime}\right)^{\sigma} ; \mathcal{T}_{\Lambda}\right) \\
& \operatorname{R} f_{*}^{\sigma}: \operatorname{Perf}_{?}^{\mathrm{ULA}}\left(Y^{\sigma} ; \mathcal{T}_{\Lambda}\right) \rightarrow \operatorname{Perf}_{?}^{\mathrm{ULA}}\left(\left(Y^{\prime}\right)^{\sigma} ; \mathcal{T}_{\Lambda}\right)
\end{aligned}
$$

Proposition 5.2.10. Let $f: Y \rightarrow Y^{\prime}$ be a $\Sigma$-equivariant morphism of the type in Notation 5.2.7. Then the following diagrams canonically commute:

Proof. We give the argument for the first diagram, the second being similar $\sqrt{6}$. We may base change to the $\Sigma$-fixed locus of $Y^{\prime}$, and therefore assume that $\Sigma$ acts trivially on $Y^{\prime}$. Let $i: Y^{\sigma} \hookrightarrow Y$ be the inclusion of the $\Sigma$-fixed points and $j: U \hookrightarrow Y$ be the complementary open embedding. For $\mathcal{F} \in D_{?}^{\mathrm{ULA}}(Y ; \Lambda)^{B \Sigma}$ consider the exact triangle

$$
j!j^{*} \mathcal{F} \rightarrow \mathcal{F} \rightarrow i_{*} i^{*} \mathcal{F}
$$

Since $\Sigma$ acts freely on $U$, Corollary $3.4 .6(1)$ implies that $R f_{!} j_{!} j^{*} \mathcal{F} \in \operatorname{Perf}{ }_{?}^{U L A}\left(Y^{\prime} ; \Lambda[\Sigma]\right)$, hence projects to 0 in $\operatorname{Perf}_{?}^{\mathrm{ULA}}\left(Y^{\prime} ; \mathcal{T}_{\Lambda}\right)$. Therefore the map $\mathrm{R} f_{!} \mathcal{F} \rightarrow \mathrm{R} f_{!} i_{*} i^{*} \mathcal{F}$ projects to an isomorphism in $\operatorname{Perf}_{?}^{\mathrm{ULA}}\left(Y^{\prime} ; \mathcal{T}_{\Lambda}\right)$.
5.3. Relative Tate-parity sheaves. We now develop an analogous theory to $\$ 5.1$ in the setting of the small Tate category, inspired by work of Leslie-Lonergan [L21 which does this for the classical affine Grassmannian. We note that it is important here to take integral coefficients in order to have any hope of parity vanishing properties, because of Example 3.7.1.

[^5]5.3.1. Krull-Schmidt property. Let $\mathbb{O}:=W(k)$, so $k=\mathbb{O} / \ell$. Note that we take $|I|=1$ below. Recall (cf. (2.7) that we write
$$
\mathbb{F}: D_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)^{\mathrm{bd}} \rightarrow D_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; k\right)^{\mathrm{bd}}
$$
for the change-of-coefficients functor.
The following Lemma is parallel to [LL21, Proposition 4.6.1].
Lemma 5.3.1. Let $\mathcal{F}, \mathcal{G} \in D_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)^{\text {bd }}$. Then there is a natural isomorphism

Proof. We have

$$
\mathcal{H o m}_{\operatorname{Perf}_{(L+H)}^{\mathrm{ULA}}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\mathrm{bd}}(\mathbb{T} \mathcal{F}, \mathbb{T} \mathcal{G}) \cong \mathbb{T}\left(\mathcal{H o m}_{\left.D_{(L+H)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)^{\mathrm{bd}}(\mathcal{F}, \mathcal{G})\right) . . . .}\right.
$$

As in Example 3.7.4, for any $\mathcal{E} \in D_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)^{\text {bd }}$, we have

$$
\mathbb{T} \mathcal{E} \cong \operatorname{Tot}(\ldots \mathcal{E} \xrightarrow{\ell} \mathcal{E} \xrightarrow{0} \mathcal{E} \xrightarrow{\ell} \mathcal{E} \xrightarrow{0} \mathcal{E} \rightarrow \ldots) \in \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\mathrm{bd}}
$$

Noting that

$$
\operatorname{Tot}(\ldots \mathcal{E} \xrightarrow{\ell} \mathcal{E} \xrightarrow{0} \mathcal{E} \xrightarrow{\ell} \mathcal{E} \xrightarrow{0} \mathcal{E} \rightarrow \ldots) \cong \bigoplus_{i \in \mathbf{Z}} \mathbb{F} \mathcal{E}[2 i]
$$

the result then follows upon taking cohomology.
Remark 5.3.2. The proof of Lemma 5.3.1 did not use the ULA or $L^{+} H$-constructibility hypotheses.
Lemma 5.3.3. Any object $\mathcal{F} \in \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}^{1}, \mu} ; \mathcal{T}_{\mathbb{O}}\right)$ is a finite direct sum of objects of the form $\mathbb{T}(\mathbb{O})$ and $\mathbb{T}(\mathbb{O}[1])$.

Proof. The same argument as for [LL21, Theorem 5.4.1] shows that any such $\mathcal{F}$ is pulled back from the small Tate category of $S$. Then we may conclude by applying [LL21, Lemma 3.5.1], with the following remark: In [L21] the case $\ell=2$ is excluded because of [LL21, Remark 3.5.4] which claims that $\operatorname{Ext}_{\mathbf{F}_{2}}^{1}\left(\mathbf{F}_{2}, \mathbf{F}_{2}\right) \neq 0$, however this is clearly false, so we may also take $\ell=2$.
Lemma 5.3.4. The category $\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\mathrm{bd}}$ is Krull-Schmidt.
Proof. By CYZ08, Theorem A.1], a Karoubian category such that the endomorphism ring of any object is semiperfect is Krull-Schmidt. We will check the semiperfect and Karoubian conditions.

First we check that $\operatorname{End}(\mathcal{K})$ is semiperfect for any $\mathcal{K} \in \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\text {bd }}$, by showing that $\operatorname{End}(\mathcal{K})$ is a finite $k$-algebra. In fact, it follows from Lemma 5.3.3 and Lemma 5.3.1 that for any $\mathcal{K}_{1}, \mathcal{K}_{2} \in$ $\operatorname{Perf}_{(L+H)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\Phi}\right)^{\text {bd }}$, the whole Ext-algebra $\operatorname{Ext}^{\bullet}\left(\mathcal{K}_{1}, \mathcal{K}_{2}\right)$ is finite-dimensional over $k$.

Now it suffices to show that $\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\text {bd }}$ is Karoubian, i.e., all idempotents are split. According to [LC07, Proposition 2.3], in a triangulated category an idempotent of a distinguished triangle which splits on any two terms splits on the third. Therefore by devissage, we may reduce to showing that for any indecomposable object in $\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \mathrm{Div}^{1}, \mu} ; \mathcal{T}_{\mathbb{O}}\right)$, its endomorphism ring is local. By Lemma 5.3 .3 such $\mathcal{K}$ must be isomorphic to $\mathbb{T}\left(\mathbb{O}^{r}[d]\right)$ for some $d$, and then Lemma 5.3.1 computes its endomorphism algebra, which is seen to be local by inspection.
5.3.2. Relative Tate-parity complexes. We define make definitions within the small Tate category analogous to those in $\$ 5.1 .3$.
Definition 5.3.5. Let $\mathcal{K} \in \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\text {bd }}$. Fix a pariversity $\dagger: X_{*}\left(T_{H}\right) \rightarrow \mathbf{Z} / 2 \mathbf{Z}$. Below we view Tate cohomology as being indexed by $\mathbf{Z} / 2 \mathbf{Z}$.
(1) For $? \in\{*,!\}$, we say $\mathcal{K}$ is relative ?-Tate-even if for all geometric points $\bar{s} \rightarrow S$ and all $\mu \in X_{*}\left(T_{H}\right)^{+}$,

$$
\mathrm{T}^{\dagger(\mu)+1}\left(i_{\mu}^{?}\left(\left.\mathcal{K}\right|_{\bar{s}}\right)\right)=0
$$

(2) For $? \in\{*,!\}$, we say $\mathcal{K}$ is relative ?-Tate-odd if $\mathcal{K}[1]$ is relative ?-Tate-even.
(3) For $? \in\{*,!\}$, we say that $\mathcal{K}$ is relative ?-Tate-parity if $\mathcal{K}$ is either relative ?-even or relative ?-odd.
(4) We say $\mathcal{K}$ is relative Tate-even (resp. relative Tate-odd) if $\mathcal{K}$ is both relative *-Tate even (resp. odd) and relative !-Tate even (resp. odd).
(5) We say $\mathcal{K}$ is a relative Tate-parity complex if it is isomorphic within $\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\text {bd }}$ to the direct sum of a relative Tate-even complex and a relative Tate-odd complex. The full subcategory of $\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\text {bd }}$ spanned by relative Tate-parity complexes (with coefficients in $\mathcal{T}_{\mathbb{O}}$ ) is denoted $\operatorname{Par}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)$.
5.3.3. Structure theory for strictly totally disconnected $S$. Here we record several structural results about $\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\text {bd }}$ under the assumption $S$ is strictly totally disconnected. Below all Hom and Ext groups are formed in the category $\operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\text {bd }}$; we omit this for ease of notation. By arguments analogous to those in $\$ 5.1 .4$ we have the following results.

Lemma 5.3.6. Assume that $S$ is strictly totally disconnected. If $\mathcal{F} \in \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \mathrm{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{Q}}\right)^{\mathrm{bd}}$ is relative $*$-Tate-parity and $\mathcal{G} \in \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\text {bd }}$ is relative !-Tate-parity, then we have a (noncanonical) isomorphism of $k$-vector spaces

$$
\operatorname{Ext}^{\bullet}(\mathcal{F}, \mathcal{G}) \cong \bigoplus_{\mu \in X_{*}\left(T_{H}\right)^{+}} \operatorname{Ext}{ }^{\bullet}\left(i_{\mu}^{*} \mathcal{F}, i_{\mu}^{!} \mathcal{G}\right)
$$

Lemma 5.3.7. Assume that $S$ is strictly totally disconnected. If $\mathcal{F} \in \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\mathrm{bd}}$ is relative $*$-Tate-even and $\mathcal{G} \in \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\text {bd }}$ is relative !-Tate-odd, then $\operatorname{Hom}(\mathcal{F}, \mathcal{G})=0$.

Lemma 5.3.8. Assume that $S$ is strictly totally disconnected. If $\mathcal{F}, \mathcal{G} \in \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\mathrm{bd}}$ are indecomposable and either both relative Tate-even or both relative Tate-odd, and $i_{\mu}$ is the inclusion of a stratum which is open in the support of both $\mathcal{F}$ and $\mathcal{G}$, then the restriction map $\operatorname{Hom}(\mathcal{F}, \mathcal{G}) \rightarrow \operatorname{Hom}\left(i_{\mu}^{*} \mathcal{F}, i_{\mu}^{*} \mathcal{G}\right)$ is surjective.
Lemma 5.3.9. Assume that $S$ is strictly totally disconnected. Let $\mathcal{F} \in \operatorname{Perf}_{(L+H)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\mathrm{bd}}$ be an indecomposable Tate-parity complex, and let $j: U \rightarrow \mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}}$ be an inclusion of a union of strata open in the support of $\mathcal{F}$. Then $j^{*} \mathcal{F}$ is either 0 or indecomposable.

Proposition 5.3.10. Assume that $S$ is strictly totally disconnected. Let $\mathcal{F} \in \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S /} \operatorname{Div}_{X}^{1} ; \mathcal{T}_{\mathbb{O}}\right)^{\mathrm{bd}}$ be an indecomposable relative Tate-parity complex. Then $\mathcal{F}$ enjoys the following properties:
(1) $\mathcal{F}$ has support of the form $\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}, \leq \mu}$ for some $\mu \in X_{*}\left(T_{H}\right)^{+}$.
(2) The restriction $i_{\mu}^{*} \mathcal{F}$ to the open stratum in $\operatorname{supp}(\mathcal{F})$ is isomorphic $\mathbb{T}(\mathbb{O}[d])$ for some $d$.
(3) Any indecomposable relative Tate-parity complex $\mathcal{G}$ supported on $\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}, \leq \mu}$, such that $i_{\mu}^{*} \mathcal{G} \cong$ $\mathbb{T}(\mathbb{O}[d])$, is isomorphic to $\mathcal{F}$.

Definition 5.3.11 (Relative Tate-parity sheaves). Assume that $S$ is strictly totally disconnected. We say that $\mathcal{F} \in \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\text {bd }}$ is a relative Tate-parity sheaf (with respect to $\dagger$ ) if it is an indecomposable relative Tate-parity complex (with respect to $\dagger$ ). We write $\mathcal{F} \cong \mathcal{E}_{\mathrm{T}}(\mu, \mathcal{L})$ if $\mathcal{F}$ has support $\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}, \leq \mu}$ and $i_{\mu}^{*} \mathcal{F} \cong \mathbb{T}(\mathcal{L})$.
5.4. Even maps. A stratified $v$-stack is a v-stack $Y$ plus a decomposition of $Y$ into locally closed strata $i_{\mu}: Y_{\mu} \hookrightarrow Y$, such that $i_{\mu}$ is shriekable for all $\mu$. For a stratified small v-stack $Y$, such that the inclusion maps of strata are all shriekable, and a pariversity $\dagger$ (i.e., a function from the set of strata to $\mathbf{Z} / 2 \mathbf{Z}$ ), we may define (absolute) parity complexes analogously to Definition 5.1.8 (requiring the restriction to strata to have cohomology sheaves which are $\Lambda$-free local systems). We do not expect it to have good properties in general, but in this section we axiomatize the property that this notion of parity complex will be preserved under "even" maps, which is true in general.

We begin with a simple observation that provides a partial substitute for "Gysin isomorphisms" in p-adic geometry (which are not defined, due to the lack of a notion of local complete intersection).

Lemma 5.4.1. Let $i: Z \rightarrow Y$ be a shriekable map of stratified Artin v-stacks which are $\ell$-cohomologically smooth of integral $\ell$-dimension (cf. [FS21, Definition IV.1.17]). Then $i^{!}$is isomorphic to an even shift of $i^{*}$ on étale local systems on $Y$.

Proof. By base changing to an étale cover of $Y$, we reduce to showing that $i^{!} \Lambda$ is isomorphic to an even shift of $\Lambda$. Writing $\mathbb{D}_{(-)}$for the dualizing sheaf and $d, d^{\prime} \in \mathbf{Z}$ for the $\ell$-dimensions of $Y, Z$ respectively, we have

$$
i^{!} \Lambda \cong i^{!} \mathbb{D}_{Y}[-2 d] \cong \mathbb{D}_{Z}[-2 d] \cong \Lambda\left[2 d^{\prime}-2 d\right]
$$

The following Definition is in imitation of [JMW14, Definition 2.32, Definition 2.33].
Definition 5.4.2 (Even maps). Let $Y$ and $Y^{\prime}$ be stratified small v-stacks and $f: Y \rightarrow Y^{\prime}$ be shriekable. We say that $f$ is stratified if
(1) The pre-image of any stratum $Y_{\lambda}^{\prime} \hookrightarrow Y^{\prime}$ is a union of strata of $Y$.
(2) For any stratum $Y_{\mu} \subset Y$ lying over any stratum $Y_{\lambda}^{\prime} \subset Y^{\prime}$, the restricted map of strata $f_{\lambda}^{\mu}: Y_{\mu} \rightarrow Y_{\lambda}^{\prime}$ is $\ell$-cohomologically smooth with integral $\ell$-dimension.
We further say that $f$ is even if for all $\mu, \lambda$ and any $\Lambda$-free étale local system $\mathcal{L}$ on $Y_{\lambda}^{\prime}$, the complex $\mathrm{R}^{i}\left(f_{\lambda}^{\mu}\right)_{*}(\mathcal{L})$ is $\Lambda$-free and vanishes for odd $i$.

The significance of even maps lies in the fact that their direct image preserves parity, as in the following Proposition.

Proposition 5.4.3. Let $Y, Y^{\prime}$ be stratified Artin $v$-stacks and let $f: Y \rightarrow Y^{\prime}$ be an even stratified map (hence shriekable by definition). Suppose that all strata of $Y, Y^{\prime}$ are $\ell$-cohomologically smooth with integral $\ell$-dimension. Let $\dagger$ be a pariversity on $Y^{\prime}$, and define the pullback pariversity $\dagger_{Y}$ on $Y$ via $\dagger_{Y}(\mu):=\dagger(\lambda)$ if $f$ carries $Y_{\mu}$ to $Y_{\lambda}^{\prime}$.
(1) If $f$ is proper and $\mathcal{K} \in D_{e ́ t}^{b}(Y ; \Lambda)$ is a $\dagger_{Y}$-parity complex, then $\mathrm{R} f_{*}(\mathcal{K}) \in D_{e t t}^{b}\left(Y^{\prime} ; \Lambda\right)$ is a $\dagger$-parity complex.
(2) If $f$ is smooth of integral $\ell$-dimension and $\mathcal{K} \in D_{\text {et }}^{b}\left(Y^{\prime} ; \Lambda\right)$ is a $\dagger$-parity complex, then $f^{*} \mathcal{K} \in D_{\text {et }}^{b}(Y ; \Lambda)$ is $a \dagger_{Y}$-parity complex.

Proof. (1) The statement and argument are the same as for JMW14, Proposition 2.34, so we just sketch it. Using proper base change, we calculate $i_{\lambda}^{*} \mathrm{R} f_{!} \mathcal{K}$ and $i_{\lambda}^{!} \mathrm{R} f_{*} \mathcal{K}$ by stratifying the fibers by $Y_{\mu}$, and calculating the cohomology of fibers in terms of cohomology of strata using excision sequences. This equips $i_{\lambda}^{*} R f_{!} \mathcal{K}$ with a filtration whose associated graded is a direct sum of pieces of the form $\mathrm{R}\left(f_{\lambda}^{\mu}\right)!i_{\mu}^{*} \mathcal{K}$, so its cohomology sheaves are $\Lambda$-free and vanish in the correct parity of degrees by the definition of an even map. The story is similar for $i_{\lambda}^{!} \mathrm{R} f_{*}$.
(2) It is immediate from the definitions that $f^{*} \mathcal{K}$ is $*$-parity with respect to $\dagger_{Y}$. Consider the commutative diagram

where the right square is Cartesian. Suppose $\mathcal{K} \in D_{\text {ett }}^{b}\left(Y^{\prime} ; \Lambda\right)$ is t-parity. Since $f$ is smooth of integral $\ell$-dimension, $\left(i_{\lambda}^{\prime}\right)^{!} f^{*} \mathcal{K} \cong f_{\lambda}^{*} i_{\lambda}^{!}$has locally constant $\Lambda$-free cohomology sheaves, which can only be non-zero in degrees congruent to $\dagger(\lambda) \bmod 2$. By Lemma 5.4.1. the same holds for $\left(i_{\lambda}^{\mu}\right)^{!}\left(i_{\lambda}^{\prime}\right)^{!} f^{*} \mathcal{K} \cong i_{\mu}^{!} f^{*} \mathcal{K}$, so $f^{*} \mathcal{K}$ is also !-parity with respect to $\dagger_{Y}$.
5.5. Demazure resolutions. We will show the existence of parity sheaves in the case where $S$ factors over a geometric point $\operatorname{Spd} C$. We first recall the notions of parahoric group schemes and their partial affine flag varieties in the context of $\mathrm{B}_{\mathrm{dR}}^{+}$-affine Grassmannians, following [FS21, §VI.5]. Let $S$ be a small v-stack and $S \rightarrow \operatorname{Div}_{X}^{1}$ a map factoring over $\operatorname{Spd} C$ where $C=\widehat{\bar{E}}$. Let $A:=W_{\mathcal{O}_{E}}\left(\mathcal{O}_{C^{b}}\right)$. For a subset $J$ of affine simple roots there is a parahoric group scheme $\mathcal{P}_{J} \rightarrow G_{A}$, and we define $L^{+} \mathcal{P}_{J} / \operatorname{Spd} \mathcal{O}_{C}$ by $L^{+} \mathcal{P}_{J}\left(R, R^{+}\right)=\mathcal{P}_{J}\left(\mathrm{~B}_{\mathrm{dR}}^{+}\left(R^{\sharp}\right)\right)$.

Now we define Bott-Samelson varieties in parallel to [JMW14, §4.1]. Fix a chain $J_{\bullet}$ of subsets of the affine simple roots of $G$,

For $(1 \leq i \leq k \leq n)$, we define

$$
\operatorname{Gr}_{J_{\bullet}}^{(i, \ldots, k)}=L G \times \times^{L^{+}} \mathcal{P}_{I_{i}}\left(L^{+} \mathcal{P}_{J_{i+1}}\right) \times \times^{L^{+}} \mathcal{P}_{I_{i+1}} \times \ldots \times\left(L^{+} \mathcal{P}_{J_{k-1}}\right) \times^{L^{+} \mathcal{P}_{I_{k-1}}}\left(L^{+} \mathcal{P}_{J_{k}}\right) /\left(L^{+} \mathcal{P}_{I_{k}}\right)
$$

and the Bott-Samelson variety

$$
\mathrm{BS}_{J .}^{(i, \ldots, k)}=\left(L^{+} \mathcal{P}_{J_{i}}\right) \times^{L^{+} \mathcal{P}_{I_{i}}}\left(L^{+} \mathcal{P}_{J_{i+1}}\right) \times^{L^{+} \mathcal{P}_{I_{i+1}}} \times \ldots \times\left(L^{+} \mathcal{P}_{J_{k-1}}\right) \times^{L^{+} \mathcal{P}_{I_{k-1}}}\left(L^{+} \mathcal{P}_{J_{k}}\right) /\left(L^{+} \mathcal{P}_{I_{k}}\right)
$$

where the action maps are given by the same formulas as in [JMW14, p.1201]. There is an obvious closed embedding $\mathrm{BS}_{J_{\bullet}}^{(i, \ldots, k)} \hookrightarrow \operatorname{Gr}_{J_{\bullet}}^{(i, \ldots, k)}$ induced by the closed embedding $L^{+} \mathcal{P}_{J_{i}} \hookrightarrow L G$.
Example 5.5.1. If $I_{i}=\emptyset$ for all $i$, and $J_{i}=\left\{j_{i}\right\}$ is a singleton with corresponding simple reflection $s_{j_{i}}$, then $\mathrm{BS}_{J_{\bullet}}^{(i, \ldots, k)}=\mathrm{Dem}_{\dot{w}, S}$ is the Demazure variety from [FS21, Definition VI.5.6] for $\dot{w}=s_{j_{i}} s_{j_{2}} \ldots s_{j_{k}} \in W_{\text {aff }}$ (the affine Weyl group of $G$ ).

Consider $L G / L^{+} \mathcal{P}_{I}$ with the stratification by left $L^{+} \mathcal{P}_{I^{\prime}}$-orbits for some $\mathcal{P}_{I^{\prime}}$. Note that if $I \subset J$, then there is a natural map

$$
\pi: L G / L^{+} \mathcal{P}_{I} \rightarrow L G / L^{+} \mathcal{P}_{J}
$$

which is stratified and even (in particular shriekable), as well as proper. For any $I$, a maximal proper choice of $J$ gives a map from $L G / L^{+} \mathcal{P}_{I}$ to an affine Grassmannian $\mathrm{Gr}_{G, C}$, and we use it to pull back to the dimension pariversity to $L G / L^{+} \mathcal{P}_{I}$. Note that $\operatorname{Gr}_{J_{\bullet}}^{(i, \ldots, k)}$ maps to $\mathrm{Gr}_{G, C}$ via projection to its first factor; this map is again stratified and even, and we use it to pull back the pariversity $\dagger$. Below, "parity" will always refer to this pariversity.
Lemma 5.5.2. If $I \subset J$, and $I^{\prime} \subset J^{\prime}$, the projection map

$$
\pi: L G / L^{+} \mathcal{P}_{I} \rightarrow L G / L^{+} \mathcal{P}_{J}
$$

is an even stratified map (where the source is equipped with the stratification by left $L^{+} \mathcal{P}_{I^{\prime}}$-orbits, and the target equipped with the stratification by left $L^{+} \mathcal{P}_{J^{\prime}}$-orbits), which is both proper and $\ell$-cohomologically smooth of integral $\ell$-dimension.

Proof. The map $\pi$ is a torsor for the diamond of a partial flag variety of $G$, hence it is proper and $\ell$ cohomologically smooth of integral $\ell$-dimension. It is also evidently stratified, and even because the cohomology of partial flag varieties is concentrated in even degrees.

As in JMW14, p.1201] there is a commutative diagram

with all squares being Cartesian; this last fact can be checked on geometric points, which then reduces as in the proof of Proposition 4.1 .2 to the analogous statement for classical affine Grassmannians, which is in JMW14.
Lemma 5.5.3. For the map $f: \mathrm{BS}_{J_{\mathbf{0}}}^{(1,2, \ldots, n)} \rightarrow L^{+} G / L^{+} \mathcal{P}_{I_{n}}$ which is the composite of the top row of (5.8), we have $\mathrm{R} f_{*} \Lambda \in D_{L^{+} \mathcal{P}_{I_{0}}}\left(L G / L^{+} \mathcal{P}_{I_{n}}\right)$ is a relative parity complex.

Proof. Repeatedly apply proper base change to rewrite $\mathrm{R} f_{*} \Lambda$ in terms of pushforward and pullbacks along the right edge of (5.8). Then all the maps involved are of the kind considered in Lemma 5.5.2, so their pullbacks and pushforwards preserve parity by Proposition 5.4.3.

Proposition 5.5.4. Assume $S=\mathrm{Spa}\left(C, C^{+}\right)$. Each orbit closure of the $L^{+} \mathcal{P}_{I^{-}}$action on $L G / L^{+} \mathcal{P}_{J}$ supports a parity sheaf.

Proof. For any such orbit closure $\bar{O}$, we claim that we can find some $J_{\bullet}$ with $I_{0}=I$ and $I_{n}=J$ such that the Bott-Samelson variety $f: \operatorname{BS}_{J_{\bullet}}^{(1, \ldots, n)} \rightarrow L G / \mathcal{P}_{J}$ has image equal to $\bar{O}$. Then by Lemma 5.5.3, $\mathrm{R} f_{*} \Lambda$ is a parity complex with full support on $\bar{O}$, hence it has an indecomposable summand with full support on $\bar{O}$.

Now to establish the claim: in the proof of [JMW14, Theorem 4.6], it is explained how to find such a map in the analogous situation for classical affine Grassmannians. We take the same combinatorial data $J_{0}$. To check that the image is as desired, it suffices to check on geometric points, and then this reduces to the classical case as in the proof of Proposition 4.1.2.

Corollary 5.5.5. If $\mathcal{F}, \mathcal{G} \in \operatorname{Par}^{U L A}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)$, then their convolution $\mathcal{F} \star \mathcal{G}$ lies in $\operatorname{Par}^{U L A}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)$.
Proof. The statement immediately reduces to the case where $S=\mathrm{Spa}\left(C, C^{+}\right)$. There the proof is similar to the proof of JMW14, Theorem 4.8], so we will just sketch it. By the proof of Proposition 5.5.4, any parity sheaf is up to shift a summand of $\mathrm{R} f_{*} \Lambda$ for some Bott-Samelson resolution $f: \mathrm{BS}_{J_{\bullet}}^{(1, \ldots, n)} \rightarrow L G / \mathcal{P}_{J}$. Therefore it suffices to show that for two such Bott-Samelson resolutions $f_{1}, f_{2}$ for $J_{\bullet}^{1}$ and $J_{\bullet}^{2}$, the convolution $\left(\mathrm{R} f_{1 *} \Lambda\right) \star\left(\mathrm{R} f_{2 *} \Lambda\right)$ is parity. But we have

$$
\begin{equation*}
\left(\mathrm{R} f_{1 *} \Lambda\right) \star\left(\mathrm{R} f_{2 *} \Lambda\right) \cong \mathrm{R} f_{*} \Lambda \tag{5.9}
\end{equation*}
$$

where $f$ is the Bott-Samelson resolution associated to the concatenation of $J_{\bullet}^{1}$ and $J_{\bullet}^{2}$, so it is a parity complex by Lemma 5.5.3.
5.6. Modular reduction. We now establish some properties of relative parity sheaves under change-ofcoefficients, parallel to [JMW14, §2.5] and [LL21, §5.6].

Lemma 5.6.1. Let $\mathbb{F}$ denote the change-of-coefficients functor

$$
\mathbb{F}=k \stackrel{L}{\otimes}(-): D_{(L+G)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)^{\mathrm{bd}} \rightarrow D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right)^{\mathrm{bd}}
$$

Let $\mathcal{E} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)^{\mathrm{bd}}$.
(1) $\mathcal{E}$ is relative ?-even (resp. odd) if and only if $\mathbb{F E}$ is relative ?-even (resp. odd).
(2) Assume $S$ is strictly totally disconnected. If $\mathcal{E}=\mathcal{E}(\mu, \mathcal{L}) \in \operatorname{Par}^{U L A}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)$ is a relative parity sheaf, then $\mathbb{F E}$ is a relative parity sheaf and we have

$$
\mathbb{F} \mathcal{E}(\mu, \mathcal{L}) \cong \mathcal{E}(\mu, \mathbb{F} \mathcal{L})
$$

Proof. (1) It is immediate from the definitions that $i^{?} \mathbb{F}(\mathcal{E}) \cong \mathbb{F}\left(i^{?} \mathcal{E}\right)$, so $\mathcal{E}$ is ?-even (resp. odd) implies that $\mathbb{F} \mathcal{E}$ is ?-even (resp. odd). The converse follows from the assumption that $\mathcal{E}$ has $\mathbb{O}$-free stalks and costalks, so the cohomology sheaves of $\mathcal{E}$ are supported in the same degrees as the cohomology sheaves of $\mathbb{F} \mathcal{E}$.
(2) By (1), $\mathbb{F} \mathcal{E}$ is a parity complex. The remaining content is that $\mathbb{F} \mathcal{E}$ is indecomposable if $\mathcal{E}$ is indecomposable. Equivalently by Lemma 5.1.6, we need to show that if $\operatorname{End}(\mathcal{E})$ is local then $\operatorname{End}(\mathbb{F} \mathcal{E})$ is local. Indeed, we have $\operatorname{End}(\mathbb{F} \mathcal{E}) \cong k \otimes_{\mathbb{Q}} \operatorname{End}(\mathcal{E})$ by Lemma 5.1.11. This shows that locality of $\operatorname{End}(\mathcal{E})$ implies locality of $\operatorname{End}(\mathbb{F} \mathcal{E})$, because a quotient of a local ring is local.

We next explain that the functor $\mathbb{T}=\mathbb{T}^{*} \epsilon^{*}$ from Definition 5.2 .4 has similar properties to modular reduction.

Proposition 5.6.2. Let $\mathcal{E} \in D_{(L+H)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)^{\mathrm{bd}}$.
(1) If $\mathcal{E} \in D_{(L+H)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)^{\mathrm{bd}}$ is relative even (resp. odd), then $\mathbb{T} \mathcal{E} \in \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\mathrm{bd}}$ is relative Tate-even (resp. odd).
(2) Assume $S$ is strictly totally disconnected. If $\mathcal{E} \cong \mathcal{E}(\mu, \mathcal{L}) \in \operatorname{Par}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)$ is a relative parity sheaf, and

$$
\begin{equation*}
\operatorname{Hom}_{D_{(L+H)}^{\mathrm{ULA}}}\left(\operatorname{Gr}_{\left.H, S / \operatorname{Div}_{X}^{1} ; \mathbb{O}\right)^{\mathrm{bd}}}(\mathcal{E}, \mathcal{E}[n])=0 \text { for all } n<0\right. \tag{5.10}
\end{equation*}
$$

then $\mathbb{T} \mathcal{E} \in \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\text {bd }}$ is a relative Tate-parity sheaf and we have

$$
\mathbb{T} \mathcal{E}(\mu, \mathcal{L}) \cong \mathcal{E}_{\mathrm{T}}(\mu, \mathcal{L})
$$

Proof. As explained in $\$ 5.2 .3$ the operation $\mathbb{T}$ is compatible with formation of $i_{\mu}^{*}$ or $i_{\mu}^{!}$. Hence to prove (1) we reduce to showing that $\mathrm{T}^{2} \epsilon^{*} \mathbb{( O )}$ vanishes in odd degree, which was seen in Example 3.7.1.

For (2), we just need to check that $\mathbb{T} \mathcal{E}$ is indecomposable. By Lemma 5.3.4, this is equivalent to the endomorphism ring of $\mathbb{T} \mathcal{E}$ being local. Applying Lemma 5.3.1 to $\mathcal{F}=\mathcal{G}=\mathcal{E}$, we have

$$
\begin{equation*}
\operatorname{Hom}_{\operatorname{Perf}_{(L+H)}^{\mathrm{ULA}}}\left(\operatorname{Gr}_{H, S / \mathrm{Div}_{X}^{1}} ; \mathcal{T}_{\oplus}\right)^{\mathrm{bd}}(\mathbb{T} \mathcal{E}, \mathbb{T} \mathcal{E})=\bigoplus_{i \in \mathbf{Z}} \operatorname{Hom}_{D_{(L+H)}^{\mathrm{ULA}}}\left(\operatorname{Gr}_{H, S / \mathrm{Div}_{X}^{1}} ; k\right)^{\mathrm{bd}}(\mathbb{F} \mathcal{E}, \mathbb{F} \mathcal{E}[2 i]) \tag{5.11}
\end{equation*}
$$

 the RHS of (5.11) indexed by $i=0$ is local, and by hypothesis (5.10) the summands of (5.11) indexed by $i<0$ vanish. This implies the desired locality of the graded algebra (5.11).
5.7. The lifting functor. For strictly totally disconnected $S$, we will construct a "lifting functor" from $\operatorname{Par}{ }^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)$ to $\operatorname{Par}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; k\right)$ following [LL21, Theorem 5.6.6], which allows to lift relative Tate-parity sheaves out of the Tate category. This will be used as part of the construction of the Brauer functor.

Definition 5.7.1 (Normalized parity sheaves). Assume that $S$ is strictly totally disconnected.
For $\mu \in X_{*}\left(T_{H}\right)^{+}$, we say that a relative parity sheaf $\mathcal{E}(\mu, \mathcal{L}) \in \operatorname{Par}^{U L A}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)$ (resp. relative Tate-parity sheaf $\left.\mathcal{E}_{\mathrm{T}}(\mu, \mathcal{L}) \in \operatorname{Par}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)\right)$ is normalized if $\mathcal{L} \cong \Lambda\left[\left\langle 2 \rho_{H}, \mu\right\rangle\right] \quad$ (resp. $\mathcal{L} \cong$ $\left.\mathbb{T}\left(\mathbb{O}\left[\left\langle 2 \rho_{H}, \mu\right\rangle\right]\right)\right)$.

A normalized (Tate-)parity complex is a finite direct sum of (Tate-)parity sheaves with no shifts.
We denote the full subcategory of normalized relative parity complexes (resp. normalized relative Tateparity complexes) by $\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right) \subset \operatorname{Par}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)\left(\operatorname{resp} . \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right) \subset\right.$ $\left.\operatorname{Par}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)\right)$.

The point of the normalization is to plausibly match the behavior of relative perverse sheaves. Indeed, in the next section we will prove:
Theorem 5.7.2. Assume $S$ is strictly totally disconnected. Suppose $\ell>b(\check{H})$, the supremum of $b(\check{\Phi})$ from Figure 1 over all root systems $\check{\Phi}$ of simple factors of $\check{H}$. For $\Lambda \in\{\mathbb{O}, k\}$, a normalized parity sheaf $\mathcal{E}\left(\mu, k\left[\left\langle 2 \rho_{H}, \mu\right\rangle\right]\right) \in \operatorname{Par}_{\mathbf{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)$ exists for all $\mu \in X_{*}\left(T_{H}\right)^{+}$, and is relative perverse.

Combining Theorem 5.7.2 and Proposition 5.6.2, under the assumption that $S$ is strictly totally disconnected and $\ell>b(\check{H})$ we have that $\mathcal{E}(\mu, \mathcal{L}) \mapsto \mathbb{T} \mathcal{E}(\mu, \mathcal{L}) \cong \mathcal{E}_{\mathrm{T}}(\mu, \mathcal{L})$ induces a bijection between normalized parity sheaves in $\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)$ and normalized Tate-parity sheaves in $\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)$.
Definition 5.7.3 (The lifting functor). Following Leslie-Lonergan, we define the lifting functor

$$
L: \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right) \rightarrow \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; k\right)
$$

which on objects sends $\mathcal{E}_{\mathrm{T}}(\lambda, \mathcal{L}) \mapsto \mathbb{F} \mathcal{E}(\lambda, \mathcal{L})$, and on morphisms projects to the summand indexed by $i=0$ in (5.7). By design, the functor $L$ fits into a commutative triangle

Remark 5.7.4. Presumably Leslie-Lonergan chose the name "lifting functor" because it takes objects in the Tate category, a Verdier quotient of a derived category of sheaves, to objects in a derived category of sheaves. Note however that the source of $L$ is the integral version of the Tate category, which is $k$-linear (like the target of $L$ ). The triangle (5.12) suggests that $L$ behaves like an intermediate change-of-coefficients functor.

Note that if $S$ is strictly totally disconnected and $\ell>b(\check{H})$, then all objects of $\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)$ are perverse by Theorem 5.7.2, hence have canonical equivariant structures, which allow us to view them in $D_{\text {êt }}^{\mathrm{ULA}}\left(\mathcal{H}^{\mathrm{ck}}{\mathrm{H}, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)^{\mathrm{bd}}$. Therefore, their convolution is defined. This endows $\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)$ with a monoidal structure $\star$.

Lemma 5.7.5. Assume $S$ is strictly totally disconnected and $\ell>b(\check{H})$. Then the functor $L$ admits a canonical monoidal structure making (5.12) into a commutative diagram of monoidal functors.
Proof. The functor $\mathbb{F}$ is monoidal, which means that there is a commutative square

with the natural transformation satisfying coherence data. Also $\mathbb{T}$ is monoidal, which entails the top commutative square in the diagram below.

In the top square of (5.14, the vertical arrows are essentially surjective by Theorem 5.7.2. The maps on morphisms are given by Lemma 5.3.1. The outer square is equivalent to (5.13) by (5.12). Hence the natural isomorphisms making the upper and outer squares commute, which are part of the monoidal structures of $\mathbb{F}$ and $\mathbb{T}$, induce a natural transformation making the lower square commute. In other words, this constructs a natural isomorphism

$$
L(\mathcal{F} \star \mathcal{G}) \cong L(\mathcal{F}) \star L(\mathcal{G})
$$

for all $\mathcal{F}, \mathcal{G} \in \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)$. The coherence data is similarly induced from those of $\mathbb{F}$ and $\mathbb{T}$.

## 6. Tilting modules and the Geometric Satake equivalence

In this section we show that normalized relative parity sheaves are relative perverse when $\ell$ is not too small, and establish that they correspond to tilting modules under the Geometric Satake equivalence. The results are parallel to those of Juteau-Mautner-Williamson in [JMW16], and we follow their proof strategy, but we also have to supply new arguments for some steps.

In fact, the majority of this section is spent on the case of tilting modules with quasi-minuscule highest weight, which occupies only six sentences in JMW16. This is because the singularities of quasi-minuscule Schubert varieties in the classical affine Grassmannians are understood, and smooth-locally equivalent to those of the minimal orbit in the nilpotent cone of $\mathfrak{g}$. At present we do not such statements in p-adic geometry. We will instead degenerate to the Witt vector affine Grassmannian and study resolutions of the quasi-minuscule Schubert varieties there constructed by Zhu Zhu17. Using the intersection forms introduced by Juteau-Mautner-Williamson JMW14 to analyze the failure of the Decomposition Theorem with modular coefficients, we compare the (failure of the) Decomposition Theorem for these resolutions with the parallel situation on the equicharacteristic affine Grassmannian, deducing that the behavior must be "the same" in a suitable sense.

We note that for the classical affine Grassmannians, Mautner-Riche MR18 have proven the relevant statements, relating normalized parity sheaves to tilting modules, in the optimal generality, improving on JMW16. However, the proof of Mautner-Riche relies on various techniques that have not yet been developed in the setting of $p$-adic geometry. Hence our results here are to some extent a "proof of concept", and we leave the optimization of technical hypotheses for future work.

We begin in $\S 6.1$ with some recollections and elaborations on the Geometric Satake equivalence of FarguesScholze. Then in $\$ 6.2$ we formulate the main results relating parity sheaves and tilting modules through this equivalence. In 6.3 we begin the proof, reducing it to the case of quasi-minuscule highest weight. Finally, $\$ 6.4$ completes the proof of this case.

Throughout this section we abbreviate $\operatorname{Gr}_{G, C}:=\operatorname{Gr}_{G, \operatorname{Spa}\left(C, C^{+}\right) / \operatorname{Div}_{X}^{1}}$ and $d_{\mu}:=\left\langle 2 \rho_{G}, \mu\right\rangle$.
6.1. The Geometric Satake equivalence. We first record some generalities on the Geometric Satake equivalence. Let $S$ be any small v-stack over $\left(\operatorname{Div}_{X}^{1}\right)^{I}$. We denote the Satake category $\operatorname{Sat}\left(\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right) \subset$ $D_{\text {êt }}^{\mathrm{ULA}}\left(\mathcal{H}^{\mathrm{Ck}}{\mathrm{G}, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} / \Lambda\right)^{\text {bd }}$ to be the full subcategory spanned by flat perverse sheaves over $S$. By the same argument as for [FS21, Proposition VI.7.2], the pullback functor

$$
\operatorname{Sat}\left(\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right) \rightarrow D_{(L+G)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{I}} ; \Lambda\right)^{\mathrm{bd}}
$$

is fully faithful, so we may regard $\operatorname{Sat}\left(\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right) \subset D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right)^{\mathrm{bd}}$.
For a v-stack $S$, we let $\operatorname{Loc}(S ; \Lambda)$ be the category of $\Lambda$-free étale local systems on $S$. Let $\pi_{G, S}: \operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} \rightarrow$ $S$ be the natural projection. In [FS21, §VI.7], Fargues-Scholze establish the Geometric Satake equivalence,

$$
\begin{equation*}
\operatorname{Sat}\left(\operatorname{Gr}_{G,\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right) \cong \operatorname{Rep}_{\operatorname{Loc}\left(\left(\operatorname{Div}_{X}^{1}\right)^{I} ; \Lambda\right)}(\check{G}) \tag{6.1}
\end{equation*}
$$

where the right side is the category of representations of a certain reductive group object in the category $\operatorname{Loc}\left(\left(\operatorname{Div}_{X}^{1}\right)^{I} ; \Lambda\right)$. The equivalence is symmetric monoidal, with the underlying monoidal structure given by convolution on the left and tensor product on the right, and carries the fiber functor $\bigoplus_{i} \mathrm{R}^{i} \pi_{G, \mathrm{Div}_{X}}$ on the left to the forgetful functor on the right.

The category $\operatorname{Loc}\left(\operatorname{Div}_{X}^{1} ; \Lambda\right)$ is symmetric monoidal under tensor product. Note that there is an action of $\operatorname{Loc}\left(\operatorname{Div}_{X}^{1} ; \Lambda\right)$ on $\operatorname{Sat}\left(\operatorname{Gr}_{G, \operatorname{Div}_{X}^{1}} ; \Lambda\right)$ via pullback and tensoring. Pullback also defines a symmetric monoidal functor $\operatorname{Loc}(S ; \Lambda) \rightarrow \operatorname{Sat}\left(\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{1} ;} ; \Lambda\right)$.

Lemma 6.1.1. The natural functor

$$
\operatorname{Sat}\left(\operatorname{Gr}_{G, \operatorname{Div}_{X}^{1}} ; \Lambda\right) \otimes_{\operatorname{Loc}\left(\operatorname{Div}_{X}^{1} ; \Lambda\right)} \operatorname{Loc}(S ; \Lambda) \rightarrow \operatorname{Sat}\left(\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{1}} ; \Lambda\right)
$$

is a monoidal equivalence with respect to the convolution product.
Proof. By descent, we may reduce to the case where $G$ is split, say with maximal torus $T$. The functor is fully faithful, using that the formation of $\mathcal{R H}$ om commutes with base change [FS21, Corollary VI.6.6]. For essentially surjectivity: the Schubert stratification induces a compatible semi-orthogonal decomposition on both sides, and it suffices to see that the functor induces an equivalence on each piece of the decomposition. On the piece indexed by $\mu \in X_{*}(T)^{+}$it takes the form

$$
\underbrace{\operatorname{Sat}\left(\operatorname{Gr}_{G, \operatorname{Div}_{X}^{1}, \mu} ; \Lambda\right)}_{\cong \operatorname{Loc}\left(\operatorname{Div}_{X}^{1} ; \Lambda\right)} \otimes_{\operatorname{Loc}\left(\operatorname{Div}_{X}^{1} ; \Lambda\right)} \operatorname{Loc}(S) \rightarrow \underbrace{\operatorname{Sat}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}, \mu} ; \Lambda\right)}_{\cong \operatorname{Loc}(S ; \Lambda)}
$$

and the equivalence is clear by inspection. The compatibility of the monoidal structures is evident from the definition.

Remark 6.1.2. Lemma 6.1.1 equips the convolution monoidal structure on $\operatorname{Sat}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)$ with a commutativity constraint, promoting it to a symmetric monoidal structure.

Tensoring (6.1) with $\operatorname{Loc}(S ; \Lambda)$ over $\operatorname{Loc}\left(\operatorname{Div}_{X}^{1} ; \Lambda\right)$ and applying Lemma 6.1.1 gives a symmetric monoidal equivalence

$$
\begin{equation*}
\operatorname{Sat}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right) \cong \operatorname{Rep}_{\operatorname{Loc}(S ; \Lambda)}(\check{G}) \tag{6.2}
\end{equation*}
$$

carrying the fiber functor $\bigoplus_{i} \mathrm{R}^{i} \pi_{G, S *}$ on the left to the forgetful functor on the right.

Example 6.1.3. If $S$ is strictly totally disconnected, then for $C^{\infty}(|S| ; \Lambda)$ the ring of continuous functions from $|S|$ to $\Lambda$, we have that

$$
\operatorname{Loc}(S ; \Lambda) \cong\left\{\text { finite projective } C^{\infty}(|S| ; \Lambda) \text {-modules }\right\}
$$

In particular, if $S=\mathrm{Spa}\left(C, C^{+}\right)$is a geometric point then $|S|$ is a point and 6.2 reads

$$
\operatorname{Sat}\left(\operatorname{Gr}_{G, C} ; \Lambda\right) \cong \operatorname{Rep}_{\Lambda}(\check{G})
$$

where $\check{G}$ is the usual Langlands dual group by [FS21, Theorem VI.11.1]. For general strictly totally disconnected $S$, we have

$$
\begin{equation*}
\operatorname{Rep}_{\operatorname{Loc}(S ; \Lambda)}(\check{G}) \cong \operatorname{Rep}_{\Lambda}(\check{G}) \otimes_{\Lambda}\left\{\text { finite projective } C^{\infty}(|S| ; \Lambda) \text {-modules }\right\} \tag{6.3}
\end{equation*}
$$

6.2. Parity and tilting. Recall that a representation of $\check{G}$ is called a tilting module if it has both a filtration by standard modules, and also a filtration by costandard modules (see [Jan03, Appendix E] for a reference). The tilting property is preserved by direct sum and tensor products; the latter case is a non-trivial theorem of Mathieu [Mat90], building on work of Wang and Donkin. Let $\operatorname{Tilt}_{\Lambda}(\check{G}) \subset \operatorname{Rep}_{\Lambda}(\breve{G})$ denote the full subcategory of tilting modules. For each $\mu \in X^{*}(\check{T})^{+}$there is a unique indecomposable tilting module of highest weight $\mu$, which we denote $T_{\Lambda}(\mu)$.
Definition 6.2.1. Let $b(\check{G})$ be the supremum of $b(\check{\Phi})$ defined in Figure 1 , as $\check{\Phi}$ runs over the root systems of simple factors of $\check{G}$.

We abbreviate the normalized relative parity sheaf with support $\operatorname{Gr}_{G, C, \leq \mu}$ by $\mathcal{E}(\mu):=\mathcal{E}\left(\mu, k\left[d_{\mu}\right]\right)$. Recall that $\mathcal{E}(\mu)$ exists for all $\mu \in X_{*}(T)^{+}$by Proposition 5.5.4
Theorem 6.2.2. If $\ell>b(\check{G})$, and $S=\operatorname{Spa}\left(C, C^{+}\right)$is a geometric point, then $\mathcal{E}(\mu)$ is perverse and corresponds under the Geometric Satake equivalence to $T_{k}(\mu)$. Thus, the Geometric Satake equivalence restricts to an equivalence as in the diagram below.

Theorem 6.2.2 implies the existence of relative parity sheaves for any strictly totally disconnected $S$ over $\operatorname{Div}_{X}{ }^{1}$.

Corollary 6.2.3. Let $S$ be strictly totally disconnected. Let $\Lambda=\mathbb{O}$ or $k$. If $\ell>b(\check{G})$, then the parity sheaf $\mathcal{E}\left(\mu ; \Lambda\left[d_{\mu}\right]\right)$ in $\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right)$ exists for all $\mu \in X_{*}(T)^{+}$.
Proof. Let $\mathcal{F}$ be the relative perverse sheaf on $\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}}$ corresponding under the Geometric Satake equivalence (6.2) to $T_{\Lambda}(\mu) \otimes C^{\infty}(|S| ; \Lambda)$ viewed in $\operatorname{Rep}_{\operatorname{Loc}(S ; \Lambda)}(\check{G})$ via 6.3$)$. If $\Lambda=k$, then $\mathcal{F}$ is a relative parity sheaf by Theorem 6.2.2. If $\Lambda=\mathbb{O}$, then $\mathbb{F} \mathcal{F}$ is a relative parity sheaf by the case just handled, hence $\mathcal{F}$ is a relative parity sheaf by Lemma 5.6.1.

Since $\operatorname{Sat}\left(\operatorname{Gr}_{G, C} ; k\right) \cong \operatorname{Rep}_{k}(\check{G})$ is a highest weight category, it has a notion of standard, costandard, and tilting objects. The standard objects are $\Delta_{\mu}:={ }^{\mathfrak{p}} i_{\mu!}\left(\underline{k}\left[d_{\mu}\right]\right)$ and the costandard objects are $\nabla_{\mu}:={ }^{\mathfrak{p}} i_{\mu *}\left(\underline{k}\left[d_{\mu}\right]\right)$ for all $\mu \in X_{*}(T)^{+}$, where the superscript ${ }^{\mathfrak{p}}$ refers to 0 th perverse cohomology.
Proposition 6.2.4. Suppose $\mathcal{F} \in \operatorname{Sat}\left(\operatorname{Gr}_{G, C} ; k\right)$ is relative perverse, and relative parity with respect to the dimension pariversity $\dagger_{G}$. Then $\mathcal{F}$ is tilting.

Proof. The proof is similar to that of JMW16, Proposition 3.3], substituting the results of $\$ 5$ for those of JMW14. We need to show that $\mathcal{F}$ has a standard filtration and a costandard filtration. By general homological algebra of Ringel JMW16, Theorem 3.1], $\mathcal{F}$ has a standard filtration if and only if Ext ${ }^{1}\left(\mathcal{F}, \nabla_{\mu}\right)=$ 0 for all $\mu \in X_{*}(T)^{+}$, and $\mathcal{F}$ has a costandard filtration if and only if $\operatorname{Ext}^{1}\left(\Delta_{\mu}, \mathcal{F}\right)=0$ for all $\mu \in X_{*}(T)^{+}$. By Verdier duality, it suffices to show that

$$
\operatorname{Ext}^{1}\left(\mathcal{F}, \nabla_{\mu}\right)=0 \text { for all } \mu \in X_{*}(T)^{+} .
$$

We have an exact triangle

$$
\nabla_{\mu} \rightarrow i_{\mu * \underline{k}}\left[d_{\mu}\right] \rightarrow A
$$

where $A$ lies in ${ }^{\mathfrak{p}} D^{>0}$ for the (relative) perverse t-structure. This gives a long exact sequence

$$
\ldots \rightarrow \operatorname{Hom}(\mathcal{F}, A) \rightarrow \operatorname{Ext}^{1}\left(\mathcal{F}, \nabla_{\mu}\right) \rightarrow \operatorname{Ext}^{1}\left(\mathcal{F}, i_{\mu *} \underline{k}\left[d_{\mu}\right]\right) \rightarrow \ldots
$$

The leftmost term vanishes by the axioms of a t-structure, because $\mathcal{F} \in{ }^{\mathfrak{p}} D^{0}$ while $A \in{ }^{\mathfrak{p}} D^{>0}$. The rightmost term vanishes by Corollary 5.1 .12 because $i_{\mu *} \underline{k}\left[d_{\mu}+1\right]$ is relative !-odd for the pariversity $\dagger$, while $\mathcal{F}$ is relative *-even.
6.3. Proof of Theorem 6.2.2, For $\lambda \in X_{*}(T)_{+}$, we let $\mathcal{T}(\mu)$ be the perverse sheaf corresponding under Geometric Satake to $T_{k}(\mu) \in \operatorname{Rep}_{k}(\check{G})$. Our goal is then to prove $\mathcal{E}(\mu) \cong \mathcal{T}(\mu)$ for all $\mu \in X_{*}(T)$. By Proposition 5.1.15 it suffices to show that $\mathcal{T}(\mu)$ is parity, since $\mathcal{T}(\mu)$ is evidently indecomposable and has the correct support.
6.3.1. Group-theoretic reductions. As in [JMW16, §3.4], by elementary reductions we may assume that $G$ is simple, semi-simple, and adjoint. Then $\check{G}$ is simple, semi-simple, and simply connected, so it has a system of fundamental weights $\omega_{i}$, as well a unique quasi-minuscule dominant root $\alpha_{0}$ (characterized as the unique shortest dominant root of $\check{G}$ ).
6.3.2. Basic cases. We will establish the result in the minuscule and quasi-minuscule cases as basic building blocks.
Lemma 6.3.1. If $\mu \in X_{*}(T)^{+}$is minuscule, then $\mathcal{E}(\mu) \cong \mathcal{T}(\mu) \cong \mathrm{IC}_{\mu}$.
Proof. The orbit corresponding to the minuscule coweights of $G$, so $\mathcal{T}(\mu) \cong \mathrm{IC}_{\mu} \cong k_{\operatorname{Gr}_{G, C, \mu}}\left[d_{\mu}\right]$. This is clearly parity, so it is isomorphic to $\mathcal{E}(\mu)$.

Proposition 6.3.2. Let $\alpha_{0}$ be the quasi-minuscule root of $\check{G}$. If $\ell$ is a good prime for $\check{G}$ and furthermore $\ell \nmid n+1$ in type $A_{n}$, $\ell \nmid n$ in type $C_{n}$, then we have

$$
\mathcal{E}\left(\alpha_{0}\right) \cong \mathcal{T}\left(\alpha_{0}\right) \cong \nabla_{\alpha_{0}} \cong \Delta_{\alpha_{0}} \cong \mathrm{IC}_{\alpha_{0}}
$$

The proof of Proposition 6.3 .2 will actually be quite involved (and will deviate significantly from its "classical" counterpart in JMW16, Lemma 3.7(2)], so we will assume it for now in order to complete the proof.
6.3.3. Fundamental coweights. Next we establish the result for the fundamental weights.

Lemma 6.3.3. If $\ell>b(\check{G})$, then for each fundamental weight $\omega_{i}$ we have $\mathcal{E}\left(\omega_{i}\right) \cong \mathcal{T}\left(\omega_{i}\right)$.
Proof. The proof is the same as that of [JMW16, Proposition 3.8] so we just sketch it. As explained earlier, it sssuffices to show that $\mathcal{T}\left(\omega_{i}\right)$ is a parity complex.

In type $A$, all the fundamental weights are minuscule, so the result follows immediately from Lemma 6.3.1. We henceforth assume that $\check{G}$ is not of type $A$. Then under the assumption $\ell>b(\check{G})$, we have by Lemma 6.3 .1 and Proposition 6.3.2 that if $\mu$ is minuscule or quasi-minuscule, then the Weyl module $W_{k}(\mu)=\Delta_{\mu}$ is tilting.

We shall want to make comparisons to characteristic zero so we write $W_{\mathbf{C}}(\mu)$ for the Weyl module of highest weight $\mu$ in $\operatorname{Rep}_{\mathbf{C}}(\check{G})$. We may realize the Weyl module $W_{\mathbf{C}}\left(\omega_{i}\right)$ as a direct summand of the tensor products of Weyl modules associated to minuscule or quasi-minuscule weights as in [JMW16, §3.6]; for example in type $B_{n}$ we have, referring to the notation of [JMW16, §3.6.2],

$$
\begin{equation*}
W_{\mathbf{C}}\left(\varpi_{n}\right)^{\otimes 2} \cong W_{\mathbf{C}}\left(2 \varpi_{n}\right) \oplus W_{\mathbf{C}}\left(\varpi_{n-1}\right) \oplus \ldots \oplus W_{\mathbf{C}}\left(\varpi_{1}\right) \oplus W_{\mathbf{C}}(0) \tag{6.5}
\end{equation*}
$$

Since the tensor product of tilting modules is tilting, the tensor products of Weyl modules over $k$ associated to (quasi)-minuscule weights are tilting (e.g., $W_{k}\left(\varpi_{1}\right)^{\otimes 2}$ in type $B_{n}$ ). Then Corollary 5.5.5 implies that the corresponding perverse sheaves are parity. If each fundamental Weyl module summand in these decompositions remains simple over $k$ (e.g., the $W_{k}\left(\varpi_{i}\right)$ in type $B_{n}$ ), then each is tilting and the same decomposition occurs over $k$ as over $\mathbf{C}$. Then $\mathcal{T}\left(\omega_{i}\right)$ is a direct summand of a parity complex, so it is a parity complex.

It only remains to remark that for $\ell>b(\breve{G})$ the fundamental Weyl modules remain simple; see JMW16, $\S 3.6]$ for the references.
6.3.4. The general case. The following Lemma completes the proof of Theorem 6.2.2 (modulo the proof of Proposition 6.3.2, which we complete in the next subsection).

Lemma 6.3.4. If $\ell>b(\breve{G})$, then for any $\mu \in X_{*}(T)^{+}$we have $\mathcal{E}(\mu) \cong \mathcal{T}(\mu)$.
Proof. The argument is the same as in JMW16, §3.7], so we just sketch it. We may write $\mu=\sum n_{i} \varpi_{i}$ for $n_{i} \geq 0$. The representation $\otimes T\left(\varpi_{i}\right)^{\otimes n_{i}}$ is tilting, with highest weight $\mu$, hence contains $T(\mu)$ as a summand. Therefore $\mathcal{T}(\mu)$ is a summand of $\mathcal{T}\left(\varpi_{1}\right)^{\star n_{1}} \star \ldots \star \mathcal{T}\left(\varpi_{r}\right)^{\star n_{r}}$. This convolution is parity by Corollary 5.5.5 since Lemma 6.3.3 implies that each $\mathcal{T}\left(\varpi_{i}\right)$ is parity. Therefore the summand $\mathcal{T}(\lambda)$ is also parity, so we must have $\mathcal{T}(\mu) \cong \mathcal{E}(\mu)$.
6.4. Proof of Proposition 6.3.2. We may assume that $G$ is split, so we fix a reductive extension $G / \mathcal{O}_{F}$, in which we prolong $T$ to a split maximal torus. Let $\bar{G}, \bar{T}$, etc. denote the special fibers of $G$, $T$, etc.
6.4.1. Reduction to the Witt vector affine Grassmannian. As observed already, it suffices to show that $\mathcal{T}\left(\alpha_{0}\right)$ is parity. Since $\mathcal{T}\left(\alpha_{0}\right)$ is pulled back along $\operatorname{Gr}_{G, C} \rightarrow \mathcal{H}^{c k}{ }_{G, C}$, the statement can be "degenerated" to characteristic $p$ via FS21, Corollary VI.6.7], which implies that it suffices to check the analogous statement for $\mathrm{Gr}_{G, \operatorname{Spd}} \overline{\mathbf{F}}_{q} / \operatorname{Div}_{\mathcal{Y}}^{1} \cong\left(\mathrm{Gr}_{G}^{\mathrm{Witt}}\right)^{\diamond}$ where $\mathrm{Gr}_{G}^{\mathrm{Witt}}$ is the Witt vector affine Grassmannian of [Zhu17, BS17]. Then by [Sch22, §27], it suffices to show the analogous statement on $\operatorname{Gr}_{G}^{W i t t}$ : the perverse sheaf $\mathcal{T}\left(\alpha_{0}\right)$ on $\mathrm{Gr}_{G}^{\mathrm{Witt}}$, corresponding to the tilting module $T_{k}\left(\alpha_{0}\right)$ under the Geometric Satake equivalence, is a parity complex.
6.4.2. Intersection forms. We recall the notion of intersection form from [JMW14, §3.1], adapted to our setting of perfect algebraic geometry. We work over an algebraically closed field $\mathbf{F}$ of characteristic $p$. For $Y / \operatorname{Spec} \mathbf{F}$, the Borel-Moore homology of $\widetilde{Y}$ is $\mathrm{H}_{a}^{\mathrm{BM}}(Y)=\mathrm{H}^{-2 a}\left(Y ; \mathbb{D}_{Y / \mathbf{F}}\right)$. If $Y$ is perfectly smooth of dimension $d$ over $\mathbf{F}$, then we have $\mathbb{D}_{Y / \mathbf{F}} \cong \underline{k}[2 d]$.

If $i: Z \rightarrow Y$ is a closed embedding with open complement $j: U \hookrightarrow Y$, then we have an exact triangle

$$
i_{*} \mathbb{D}_{Z / \mathbf{F}} \rightarrow \mathbb{D}_{Y / \mathbf{F}} \rightarrow j_{*} \mathbb{D}_{U / \mathbf{F}}
$$

Suppose $Y$ is perfectly smooth of dimension $d$ over $\mathbf{F}$, so the same holds for $U$. Then $\mathbb{D}_{Y / \mathbf{F}} \cong k[2 d]$ and similarly for $\mathbb{D}_{U / \mathbf{F}}$. Taking cohomology, this induces an isomorphism

$$
\mathrm{H}_{a}^{\mathrm{BM}}(Z) \cong \mathrm{H}_{Z}^{2 d-a}(Y ; k):=\mathrm{H}^{2 d-a}\left(Y ; i_{*} i^{!} k_{Y}\right)
$$

The cup product on relative cohomology gives a pairing $\mathrm{H}_{Z}^{2 d-a}(Y ; \underline{k}) \otimes \mathrm{H}_{Z}^{2 d-b}(Y ; \underline{k}) \rightarrow \mathrm{H}_{Z}^{4 d-a-b}(Y ; \underline{k})$, which translates to a pairing

$$
\begin{equation*}
\mathrm{H}_{a}^{\mathrm{BM}}(Z) \otimes \mathrm{H}_{b}^{\mathrm{BM}}(Z) \rightarrow \mathrm{H}_{a+b-2 d}^{\mathrm{BM}}(Z) \tag{6.6}
\end{equation*}
$$

under the commutative diagram

Suppose $a+b=2 d$ and $Z$ is perfectly proper. Then we have a degree map $\operatorname{deg}: \mathrm{H}_{0}^{\mathrm{BM}}(Z) \rightarrow k$, which when combined with 6.6) induces a pairing

$$
\begin{equation*}
B_{Z}^{m}: \mathrm{H}_{d-m}^{\mathrm{BM}}(Z) \otimes \mathrm{H}_{d+m}^{\mathrm{BM}}(Z) \rightarrow k \tag{6.8}
\end{equation*}
$$

This is the (analogue of the) intersection form from JMW14, §3.1], which is in turn inspired by the work of de Cataldo and Migliorini on the Hodge theory of the Decomposition Theorem. In an analogous topological setting, it measures the intersection number of a real $(d-m)$-dimensional cycle on $Z$ and a real $(d+m)$ dimensional cycle on $Z$ within the (real) $2 d$-dimensional space $Y$. We will use it to study the Decomposition Theorem with modular coefficients.
6.4.3. Splitting at the singular point. Let $\pi: \widetilde{X} \rightarrow X$ be a perfectly proper surjective map, with $\widetilde{X}$ perfectly smooth of dimension $d$. Let $x_{0} \in X$ and form the Cartesian square

Then by 6.4 .2 (taking $Y=\widetilde{X}$ and $Z=F$ ), for each $0 \leq m \leq d$ there is an intersection form

$$
\begin{equation*}
B_{F}^{m}: \mathrm{H}_{d-m}^{\mathrm{BM}}(F) \otimes \mathrm{H}_{d+m}^{\mathrm{BM}}(F) \rightarrow k \tag{6.9}
\end{equation*}
$$

Its rank controls the splitting of $\pi_{*} k_{\widetilde{X}}[d]$ in the following sense.
Lemma 6.4.1. JMW14, Proposition 3.2] The multiplicity of $i_{*} \underline{k}[m]$ as a direct summand of $\pi_{*} k_{\tilde{X}}[d]$ is equal to the rank of $B_{F}^{m}$.
6.4.4. Zhu's resolution. We will apply the preceding generalities to Zhu's resolution of the quasi-minuscule Schubert variety in $\mathrm{Gr}_{G}^{\mathrm{Witt}}$ from [Zhu17, §2.2.2]. We briefly review this notation for the reader's convenience, and to set notation. Let $\alpha_{0} \in X_{*}(T)^{+}$be the quasi-minuscule dominant coroot of $G$. We abbreviate $\mathrm{Gr}:=\operatorname{Gr}_{G}^{\text {Witt }}$. Then we have the stratification

$$
\mathrm{Gr}_{\leq \alpha_{0}}=\mathrm{Gr}_{\alpha_{0}} \sqcup \mathrm{Gr}_{0}
$$

For a root $\alpha \in X^{*}(T)$, let $U_{\alpha}$ denote the corresponding root subgroup of $G$ over $\mathcal{O}$ and fix an isomorphism $U_{\alpha}(F)$ carrying $U_{\alpha}(\mathcal{O})$ isomorphically to $\mathcal{O}$. For a real number $r \in[0,1]$, let $\mathcal{G}_{r}$ be the parahoric group scheme over $\mathcal{O}$, with $\mathcal{O}$-points the parahoric subgroup of $G(E)$ generated by $T(\mathcal{O})$ and $\varpi^{\left\lceil\left\langle r \alpha_{0}^{\vee}, \alpha\right\rangle\right\rceil} \mathcal{O} \subset E=U_{\alpha}(E)$ for all roots $\alpha$. Let $Q_{r}=L^{+} \mathcal{G}_{r}$ be the corresponding $p$-adic jet group.

Following Zhu, we define

$$
\begin{equation*}
\widetilde{\mathrm{Gr}}_{\leq \alpha_{0}}:=Q_{0} \times{ }^{Q_{1 / 4}} Q_{1 / 2} / Q_{3 / 4} . \tag{6.10}
\end{equation*}
$$

Let

$$
\pi: \widetilde{\mathrm{Gr}}_{\leq \alpha_{0}} \rightarrow \mathrm{Gr}_{\leq \alpha_{0}}
$$

be the map sending $\left(g, g^{\prime}\right)$ to $g g^{\prime} \varpi^{\alpha_{0}}$. By [Zhu17, Lemma 2.12(ii)] it restricts to an isomorphism

$$
\pi^{\circ}: Q_{0} \times{ }^{Q_{1 / 4}}\left(Q_{1 / 4} Q_{3 / 4}\right) / Q_{3 / 4} \xrightarrow{\sim} \operatorname{Gr}_{\alpha_{0}}
$$

over the open stratum, and to a contraction

$$
\begin{equation*}
\pi_{0}:\left(\bar{G} / \bar{P}_{\alpha_{0}}\right)^{p^{-\infty}} \rightarrow \mathrm{Gr}_{0}=\mathrm{pt} \tag{6.11}
\end{equation*}
$$

over the singular point, where we recall that $(-)^{p^{-\infty}}$ denotes perfection and $\bar{G}$, etc. denotes the special fiber of $G$, etc. Note that this is exactly the setup of 8 6.4.3.

All of the constructions of the preceding paragraph make sense for the equal characteristic affine Grassmannian, and yield a similar picture. We will denote the analogous objects with a superscript $\bigsqcup$.

By the same argument as for Proposition 6.2.4. in order to show that $\mathcal{T}\left(\alpha_{0}\right) \cong \mathcal{E}\left(\alpha_{0}\right)$ it suffices to show that $\mathcal{E}\left(\alpha_{0}\right)$ is perverse. In the equal characteristic situation, we already know the analogue of Proposition 6.3.2 in particular that $\mathcal{E}\left(\alpha_{0}\right)^{\natural} \cong \mathcal{T}\left(\alpha_{0}\right)^{\natural}$ is perverse. Since $\pi^{\natural}$ is even, $\pi_{*}^{\natural}\left(k\left[d_{\alpha_{0}}\right]\right)$ is a parity sheaf on $\mathrm{Gr}_{\leq \alpha_{0}}^{\natural}$. Hence we have

$$
\pi_{*}^{\natural}\left(k\left[d_{\alpha_{0}}\right]\right) \cong \mathcal{E}\left(\alpha_{0}\right)^{\natural} \oplus \mathcal{K}^{\natural}
$$

where $\mathcal{K}^{\natural} \cong \bigoplus_{m \in \mathbf{Z}} i^{\natural} k[m]^{\oplus e_{m}}$ for some collection of multiplicities $e_{m}$. Since $\pi_{*}\left(k\left[d_{\alpha_{0}}\right]\right)$ and $\pi_{*}^{\natural}\left(k\left[d_{\alpha_{0}}\right]\right)$ have the same (co)stalks at the singular point (namely the cohomology of $\bar{G} / \bar{P}_{\alpha_{0}}$, by (6.11), it suffices to show that for all $m \in \mathbf{Z}, i_{*} k[m]$ is a summand of $\pi_{*} \underline{k}\left[d_{\alpha_{0}}\right]$ with the same multiplicity $e_{m}$.
6.4.5. Reduction to rank of intersection forms. Taking $\widetilde{X}:=\widetilde{\operatorname{Gr}}_{\leq \alpha_{0}}$ and $F$ to be the fiber over $\operatorname{Gr}_{0}$, and $\widetilde{X}^{\natural}$ and $F^{\natural}$ the analogous objects for the equal characteristic affine Grassmannian, it suffices by 6.4 .3 to show that the intersection form

$$
B_{F}^{m}: \mathrm{H}_{d-m}^{\mathrm{BM}}(F) \otimes \mathrm{H}_{d+m}^{\mathrm{BM}}(F) \rightarrow k
$$

has the same rank as the intersection form

$$
B_{F^{\natural}}^{m}: \mathrm{H}_{d-m}^{\mathrm{BM}}\left(F^{\natural}\right) \otimes \mathrm{H}_{d+m}^{\mathrm{BM}}\left(F^{\natural}\right) \rightarrow k .
$$

For this it suffices to produce a commutative diagram

in which the bottom identification is compatible with the cup product.
6.4.6. Equivariant formality. Let $K$ be a pro-(perfection of)-algebraic group and $Y$ an ind-scheme with an action of $K$. We have the equivariant cohomology

$$
\mathrm{H}_{K}^{*}(Y ; k) \cong \mathrm{H}^{*}(K \backslash Y ; k)
$$

where on the RHS the quotient is taken in the sense of stacks. Recall that we say $Y$ is $K$-equivariantly formal (over $k$ ) if the Leray-Serre spectral sequence $\mathrm{H}^{*}(Y ; k) \otimes_{k} \mathrm{H}_{K}^{*}(\mathrm{pt} ; k) \Longrightarrow \mathrm{H}_{K}^{*}(Y ; k)$ degenerates at $E_{2}$, thus giving an isomorphism

$$
\mathrm{H}_{K}^{*}(Y ; k) \cong \mathrm{H}^{*}(Y ; k) \otimes_{k} \mathrm{H}_{K}^{*}(\mathrm{pt} ; k) .
$$

Lemma 6.4.2. If $\mathrm{H}^{*}(Y ; k)$ is concentrated in even degrees and $\mathrm{H}_{K}^{*}(\mathrm{pt} ; k)$ is concentrated in even degrees, then $Y$ is $K$-equivariantly formal.

Proof. The differentials in the Leray-Serre spectral sequence change parity.

Example 6.4.3. Any $K$ of the form $Q_{r}^{\natural}\left(\right.$ resp. $\left.Q_{r}\right)$ has the property that the quotient by its pro-unipotent radical is (the perfection of) a reductive subgroup of $G$. Hence if $\ell$ is not a torsion prime for $G$, then $\mathrm{H}_{K}^{*}(\mathrm{pt} ; k)$ is even for any such $K$ (cf. JMW14, §2.6]). This is implied by the condition $\ell>b(\check{G})$.

Corollary 6.4.4. Let $F, F^{\natural}, \widetilde{X}, \widetilde{X}^{\natural}$ be as in 6.4.5. Assume that $\ell$ is not a torsion prime for $G$.
(1) $F$ is $Q_{0}$-equivariantly formal over $k$, and $F^{\natural}$ is $Q_{0}^{\natural}$-equivariantly formal over $k$.
(2) $\widetilde{X}$ is $Q_{0}$-equivariantly formal over $k$, and $\widetilde{X}^{\natural}$ is $Q_{0}^{\natural}$-equivariantly formal over $k$.

Proof. Note that $F, F^{\natural}, X, X^{\natural}$ are paved by (perfections of) affine spaces, so their cohomology is concentrated in even degrees. By Example 6.4.3 the $Q_{0}$ (resp. $Q_{0}^{\natural}$ ) equivariant cohomology of a point is even under the hypothesis on $\ell$, so the statements follow from Lemma 6.4.2.

If $Y$ is $K$-equivariantly formal, then we can recover $\mathrm{H}^{*}(Y ; k) \cong \mathrm{H}_{K}^{*}(Y ; k) \otimes_{\mathrm{H}_{K}^{*}(\mathrm{pt} ; k)} k$, and similarly for cohomology with supports. Hence by Corollary 6.4.4 to produce 6.12 it suffices to produce a commutative diagram

where the bottom horizontal isomorphism is compatible with the cup product.
6.4.7. Equivariant cohomology. By definition 6.10, the $Q_{0}$-equivariant cohomology complex of $\widetilde{\mathrm{Gr}}_{\leq \alpha_{0}}$ is

$$
R \Gamma_{Q_{0}}\left(\widetilde{\mathrm{Gr}}_{\leq \alpha_{0}}\right) \cong \mathrm{R} \Gamma\left(Q_{1 / 4} \backslash Q_{1 / 2} / Q_{3 / 4}\right)
$$

We keep track of cohomology complexes so as to be able to control the cohomology with supports. We abbreviate $R(K):=\mathrm{H}_{K}^{*}(\mathrm{pt} ; k)$. Write $\mathrm{B} K$ for the classifying space $[\mathrm{pt} / K]$.
Lemma 6.4.5 (Equivariant Künneth formula). Let $K$ be a connected pro-(perfection of)-algebraic group. Let $Y_{1}$ and $Y_{2}$ be $K$-equivariant ind-(perfection of)varieties such that

$$
\operatorname{Tor}_{R(K)}^{i}\left(\mathrm{H}_{K}^{*}\left(Y_{1}\right), \mathrm{H}_{K}^{*}\left(Y_{2}\right)\right)=0 \text { for all } i
$$

Then the natural map

$$
\begin{equation*}
\mathrm{H}_{K}^{*}\left(Y_{1}\right) \otimes_{R(K)} \mathrm{H}_{K}^{*}\left(Y_{2}\right) \rightarrow \mathrm{H}_{K}^{*}\left(Y_{1} \times Y_{2}\right) \tag{6.14}
\end{equation*}
$$

is a $k$-algebra isomorphism.
Proof. The hypothesis on $K$ implies that the existence and convergence of the Eilenberg-Moore spectral sequence

$$
\operatorname{Tor}_{R(K)}^{*, *}\left(\mathrm{H}_{K}^{*}\left(Y_{1}\right), \mathrm{H}_{K}^{*}\left(Y_{2}\right)\right) \Longrightarrow \mathrm{H}_{K}^{*}\left(Y_{1} \times Y_{2}\right)
$$

The Tor-vanishing assumption then implies that this spectral sequence degenerates, concluding the proof.
Example 6.4.6. If $\ell$ is not a torsion prime of $G$, the main theorem of Dem73] says that $R(T)$ is flat over $R(G)$. It follows that for any Levi subgroup $L \subset G$ containing $T, R(L)$ is flat over $R(G)$ (since $R(L)$ is a direct summand of $R(T)$ as an $R(G)$-module).

We will now give descriptions of the equivariant cohomology of $F, \widetilde{\mathrm{Gr}}_{\leq \alpha_{0}}$, and $\operatorname{Gr}_{\alpha_{0}}$ and their $\underline{q}$-variants in the spirit of Soergel bimodule theory.

Example 6.4.7 (Zhu resolution). Assume that $\ell$ is not a torsion prime of $G$. By definition, we have

$$
Q_{0} \backslash \widetilde{\mathrm{Gr}}_{\leq \alpha_{0}}=Q_{0} \backslash Q_{0} \times^{Q_{1 / 4}} Q_{1 / 2} / Q_{3 / 4} \cong Q_{1 / 4} \backslash Q_{1 / 2} / Q_{3 / 4}
$$

From Lemma 6.4.5 and Example 6.4.6, we have a $k$-algebra isomorphism

$$
\begin{equation*}
\mathrm{R} \Gamma\left(Q_{0} \backslash \widetilde{\mathrm{Gr}}_{\leq \alpha_{0}}\right) \cong \mathrm{R} \Gamma\left(\mathrm{~B} Q_{1 / 4}\right) \otimes_{\mathrm{R} \Gamma\left(\mathrm{~B} Q_{1 / 2}\right)} \mathrm{R} \Gamma\left(\mathrm{~B} Q_{3 / 4}\right) \tag{6.15}
\end{equation*}
$$

Similarly for the $\square$ version, we have a $k$-algebra isomorphism

$$
\begin{equation*}
\mathrm{R} \Gamma\left(Q_{0}^{\natural} \backslash \widetilde{\mathrm{Gr}}_{\leq \alpha_{0}}^{\natural}\right) \cong \mathrm{R} \Gamma\left(\mathrm{~B} Q_{1 / 4}^{\natural}\right) \otimes_{\mathrm{R} \Gamma\left(\mathrm{~B} Q_{1 / 2}^{\natural}\right)} \mathrm{R} \Gamma\left(\mathrm{~B} Q_{3 / 4}^{\natural}\right) \tag{6.16}
\end{equation*}
$$

Example 6.4.8 (Open stratum). Assume that $\ell$ is not a torsion prime of $G$. According to Zhu17, Lemma 2.12(ii)], the open stratum has the group-theoretic description

$$
\begin{equation*}
Q_{0} \backslash \mathrm{Gr}_{\alpha_{0}} \cong Q_{0} \backslash Q_{0} \times^{Q_{1 / 4}}\left(Q_{1 / 4} Q_{3 / 4}\right) / Q_{3 / 4} \cong\left(Q_{1 / 4} \cap Q_{3 / 4}\right) \backslash Q_{3 / 4} / Q_{3 / 4} \tag{6.17}
\end{equation*}
$$

From Lemma 6.4.5 and Example 6.4.6, we have a $k$-algebra isomorphism

$$
\begin{equation*}
\operatorname{R\Gamma }\left(Q_{0} \backslash \operatorname{Gr}_{\alpha_{0}}\right) \cong \mathrm{R} \Gamma\left(\mathrm{~B}\left(Q_{1 / 4} \cap Q_{3 / 4}\right)\right) \otimes_{\mathrm{R} \Gamma\left(\mathrm{~B} Q_{3 / 4}\right)} \mathrm{R} \Gamma\left(\mathrm{~B} Q_{3 / 4}\right) \cong \mathrm{R} \Gamma\left(\mathrm{~B}\left(Q_{1 / 4} \cap Q_{3 / 4}\right)\right) \tag{6.18}
\end{equation*}
$$

Similarly for the $h$ version, we have a $k$-algebra isomorphism

$$
\begin{equation*}
\operatorname{R\Gamma }\left(Q_{0}^{\natural} \backslash \operatorname{Gr}_{\alpha_{0}}^{\natural}\right) \cong \operatorname{R\Gamma }\left(\mathrm{B}\left(Q_{1 / 4}^{\natural} \cap Q_{3 / 4}^{\natural}\right)\right) \otimes_{\mathrm{R} \Gamma\left(\mathrm{~B} Q_{3 / 4}^{\natural}\right)} R\left(\mathrm{~B} Q_{3 / 4}^{\natural}\right) \cong \operatorname{R\Gamma }\left(\mathrm{B}\left(Q_{1 / 4}^{\natural} \cap Q_{3 / 4}^{\natural}\right)\right) \tag{6.19}
\end{equation*}
$$

Example 6.4.9 (Closed stratum). According to [Zhu17, Lemma 2.12(ii)], the fiber $F$ has the group-theoretic description

$$
Q_{0} \backslash Q_{0} \times^{Q_{1 / 4}} Q_{1 / 4} s Q_{3 / 4} / Q_{3 / 4} \cong\left(s Q_{1 / 4} s^{-1} \cap Q_{3 / 4}\right) \backslash Q_{3 / 4} / Q_{3 / 4}
$$

where $s$ is the affine reflection corresponding to $1+\alpha_{0}$. From Lemma 6.4.5 and Example 6.4.6, we have a $k$-algebra isomorphism

$$
\begin{equation*}
\mathrm{R} \Gamma\left(Q_{0} \backslash F\right) \cong \mathrm{R} \Gamma\left(\mathrm{~B}\left(s Q_{1 / 4} s^{-1} \cap Q_{3 / 4}\right)\right) \otimes_{\mathrm{R} \Gamma\left(\mathrm{~B} Q_{3 / 4}\right)} \mathrm{R} \Gamma\left(\mathrm{~B} Q_{3 / 4}\right) \cong \mathrm{R} \Gamma\left(\mathrm{~B}\left(s Q_{1 / 4} s^{-1} \cap Q_{3 / 4}\right)\right) \tag{6.20}
\end{equation*}
$$

Similarly for the $\downarrow$ version, we have a $k$-algebra isomorphism

$$
\begin{equation*}
\operatorname{R\Gamma }\left(Q_{0}^{\natural} \backslash F^{\natural}\right) \cong \operatorname{R\Gamma }\left(\mathrm{B}\left(s Q_{1 / 4}^{\natural} s^{-1} \cap Q_{3 / 4}^{\natural}\right)\right) \otimes_{\mathrm{R} \Gamma\left(\mathrm{~B} Q_{3 / 4}^{\natural}\right)} \mathrm{R} \Gamma\left(\mathrm{~B} Q_{3 / 4}^{\natural}\right) \cong \mathrm{R} \Gamma\left(\mathrm{~B}\left(s Q_{1 / 4}^{\natural} s^{-1} \cap Q_{3 / 4}^{\natural}\right)\right) . \tag{6.21}
\end{equation*}
$$

6.4.8. Comparing mixed and equal characteristic. Now, note that for each $r \in[0,1]$, the quotient of $Q_{r}$ by its uni-potent radical $Q_{r}^{\mathrm{u}}$ is isomorphic to the quotient of $Q_{r}^{\natural}$ by its pro-unipotent radical $Q_{r}^{\natural, u}$. This induces an identification $R\left(Q_{r}\right) \cong R\left(Q_{r}^{\natural}\right)$ via the chain of isomorphisms

$$
R\left(Q_{r}\right) \stackrel{\sim}{\sim}\left(Q_{r} / Q_{r}^{\mathrm{u}}\right)=R\left(Q_{r}^{\natural} / Q_{r}^{\mathrm{\natural}, \mathrm{u}}\right) \xrightarrow{\sim} R\left(Q_{r}^{\mathrm{\natural}}\right) .
$$

Combining this with Examples 6.4.7 6.4.8, and 6.4.9, we obtain a commutative diagram of identifications

where the vertical columns are exact triangles. Furthermore, the middle and bottom horizontal identifications are symmetric monoidal, hence they induce a symmetric monoidal isomorphism of the equivariant cohomology with supports

$$
\operatorname{R} \Gamma_{Q_{0} \backslash F}\left(Q_{0} \backslash \mathrm{Gr}_{\leq \alpha_{0}}\right) \cong \mathrm{R} \Gamma_{Q_{0}^{\natural} \backslash F^{\natural}}\left(Q_{0}^{\natural} \backslash \mathrm{Gr}_{\leq \alpha_{0}}^{\natural}\right)
$$

compatibly with the identifications with the top row. This establishes the diagram (6.13), thus completing the proof of Proposition 6.3.2.

## 7. The Brauer functor and the $\sigma$-Dual homomorphism

Let $G$ be a reductive group over $E$ with an action of $\Sigma$, and let $H=G^{\sigma} \stackrel{\iota}{\rightarrow} G$. We assume that $H$ is reductive. In this section we categorify the normalized Brauer homomorphism br from the spherical Hecke algebra of $G$ to that of $H$, introduced in TV16] and recalled in $\$ 7.1$. This is defined via two steps: (1) a multiplicative norm that turns a function in the spherical Hecke algebra of $G$ into a $\Sigma$-equivariant function, and then (2) a naive restriction of functions from $G$ to $H$, which turns out to be multiplicative by a miracle of characteristic $\ell$.

Roughly speaking, Step (1) is categorified by a monoidal norm and Step (2) is categorified by the Smith operation Psm. However, Psm lands in the Tate category while we eventually want the target of the Brauer functor to be perverse sheaves, so we want to use the lifting functor from $\$ 5.7$ to lift out of the Tate category. Therefore, we need to study how Psm interacts with (Tate-)parity sheaves. This is done in $\$ 7.2$ and $\$ 7.3$, which together categorify Step (2).

Then in $\S 7.4$ we construct the Brauer functor $\widetilde{b r}$ from the Satake category of $G$ to the Satake category of $H$, which entails categorifying Step (1) and then also implementing certain extensions, from parity sheaves to all perverse sheaves (using the connection to tilting modules, plus results on abelian envelopes) and from strictly totally disconnected $S$ to $\operatorname{Div}_{X}^{1}$ (using v-descent). In $\$ 7.5$ we establish a compatibility of $\tilde{b r}$ with the constant term functor, which is needed later to show that it has good properties (e.g., additivity and exactness) and also to compute the $\sigma$-dual homomorphism in examples of interest.

In $\S 7.6$ we prove that $\widetilde{b r}$ is compatible with the Tannakian structure of the Satake categories. From this we deduce the existence of the $\sigma$-dual homomorphism. Finally, in 8.7 we bootstrap to a "multi-legged" version for Beilinson-Drinfeld Grassmannians over $\left(\operatorname{Div}_{X}^{1}\right)^{I}$.
7.1. Treumann-Venkatesh functoriality. Let $K \subset G(E)$ be an open compact subgroup. The Hecke algebra of $G$ with respect to $K$ with coefficients in $\Lambda$ is

$$
\begin{equation*}
\mathscr{H}(G, K ; \Lambda):=\operatorname{Fun}_{c}(K \backslash G(E) / K, \Lambda), \tag{7.1}
\end{equation*}
$$

the compactly supported functions on $K \backslash G(E) / K$ valued in $\Lambda$. This forms an algebra under convolution, normalized so that the indicator function $\mathbb{1}_{K}$ is the unit.

For a $\Sigma$-stable subgroup $K \subset G(E)$, we write $\iota^{*} K:=\iota^{-1}(K) \subset H(E)$. We say that a compact open subgroup $K \subset G(E)$ is a plain subgroup if the natural map $H(E) / \iota^{*} K \rightarrow[G(E) / K]^{\sigma}$ is a bijection. We may view $\mathscr{H}(G, K ; \Lambda)$ as the ring $\operatorname{Fun}_{c}^{G(E)}([G(E) / K] \times[G(E) / K], \Lambda)$ of $G(E)$-invariant (for the diagonal action) compactly supported functions (valued in $\Lambda$ ) on $[G(E) / K] \times[G(E) / K]$, under convolution.
7.1.1. The un-normalized Brauer homomorphism. Now suppose that $\Lambda=k$ has characteristic $\ell$. In this special situation, Treumann-Venkatesh observed that if $K \subset G(E)$ is a plain subgroup, then the restriction map

$$
\begin{align*}
\mathscr{H}(G, K ; k)^{\sigma} & =\operatorname{Fun}_{c}^{G(E)}([G(E) / K] \times[G(E) / K], k)^{\sigma}  \tag{7.2}\\
& \xrightarrow{\text { restrict }} \operatorname{Fun}_{c}^{H(E)}\left(\left[H(E) / \iota^{*} K\right] \times\left[H(E) / \iota^{*} K\right], k\right)=\mathscr{H}\left(H(E), \iota^{*} K ; k\right)
\end{align*}
$$

is an algebra homomorphism (cf. [Fen, Lemma 6.5] for a proof). This map was introduced in [TV16, §4] and called the (un-normalized) Brauer homomorphism. We denote it

$$
\begin{equation*}
\mathrm{Br}: \mathscr{H}(G, K ; k)^{\sigma} \rightarrow \mathscr{H}\left(H, \iota^{*} K ; k\right) \tag{7.3}
\end{equation*}
$$

We will categorify Br to an "un-normalized Brauer functor" $\mathcal{B} r$ in $\$ 7.3$.
7.1.2. Frobenius twist of algebras. Let Frob be the absolute ( $\ell$-power) Frobenius of $k$. Given a commutative $k$-algebra $A$, we denote by $A^{(\ell)}:=A \otimes_{k \text {, Frob }} k$ its Frobenius twist. The map $\phi: A \rightarrow A^{(\ell)}$ sending $a \mapsto a \otimes 1$ is a $k$-semilinear isomorphism.

If $A$ is equipped with an $\mathbf{F}_{\ell \text {-structure }} \varphi_{0}: A \cong A_{0} \otimes_{\mathbf{F}_{\ell}} k$, then there is a $k$-linear isomorphism $f_{\varphi_{0}}: A \xrightarrow{\sim}$ $A^{(\ell)}$, characterized by the property that it sends $A_{0} \subset A$ to $A_{0} \otimes 1 \subset A^{(\ell)}$ via Id $\otimes 1$. We denote by $\operatorname{Frob}_{\varphi_{0}}=f_{\varphi_{0}}^{-1} \circ \phi: A \xrightarrow{\sim} A$; it is characterized as the unique Frob-semilinear automorphism of $A$ which restricts to the identity on $A_{0}$.

Suppose $f: A \rightarrow B$ is any Frob-semilinear homomorphism (i.e., $f(\lambda a)=\lambda^{\ell} f(a)$ for $\left.\lambda \in k\right)$. Then $f$ factors uniquely through a $k$-linear homomorphism

The $k$-linear homomorphism $A \rightarrow B$ obtained by precomposing $f$ with the inverse of $\mathrm{Frob}_{\varphi_{0}}$ (i.e., the dashed arrow in the diagram above) will be called the linearization of $f$ (with respect to $\varphi_{0}$ ).

Definition 7.1.1 (The Tate diagonal). Let $A$ be a commutative $k$-algebra with an $\mathbf{F}_{\ell \text {-structure }} \varphi_{0}$. Let $\mathrm{Nm}: A \rightarrow \mathrm{~T}^{0}(A)$ be the Tate diagonal map sending $a$ to the class of $a \cdot\left({ }^{\sigma} a\right) \cdot \ldots \cdot\left(\sigma^{\ell-1} a\right)$. One checks that this is a ring homomorphism, which is evidently Frob-semilinear. Let $\mathrm{Nm}^{\left(\ell^{-1}\right)}: A \rightarrow \mathrm{~T}^{0}(A)$ be the linearization of Nm with respect to $\varphi_{0}$.
7.1.3. The normalized Brauer homomorphism. Next suppose that $\mathscr{H}(G(E), K ; k)$ and $\mathscr{H}(H(E), K ; k)$ are commutative. The Tate diagonal provides a map (cf. 3.7 for notation on Tate cohomology)

$$
\mathrm{Nm}: \mathscr{H}(G, K ; k) \xrightarrow{\sim} \mathrm{T}^{0}(\mathscr{H}(G, K ; k))=\frac{\mathscr{H}(G, K ; k)^{\sigma}}{N \cdot \mathscr{H}(G, K ; k)} .
$$

One observes that the Brauer homomorphism $\operatorname{Br}$ factors over $\mathrm{T}^{0}(\mathscr{H}(G, K ; k))$, hence we obtain a map

$$
\mathrm{Br} \circ \mathrm{Nm}: \mathscr{H}(G, K ; k) \rightarrow \mathscr{H}\left(H, \iota^{*} K ; k\right) .
$$

This map is a Frob-semilinear ring homomorphism, and the normalized Brauer homomorphism is its linearization with respect to the canonical $\mathbf{F}_{\ell \text {-structure }}$

$$
\mathscr{H}(G, K ; k) \cong \mathscr{H}\left(G, K ; \mathbf{F}_{\ell}\right) \otimes_{\mathbf{F}_{\ell}} k .
$$

Equivalently, we may write

$$
\begin{equation*}
\mathrm{br}=\operatorname{Br} \circ \mathrm{Nm}^{\left(\ell^{-1}\right)}: \mathscr{H}(G, K ; k) \rightarrow \mathscr{H}\left(H, \iota^{*} K ; k\right) \tag{7.4}
\end{equation*}
$$

Below we will categorify br, under the assumption $\ell>\max \{b(\check{G}), b(\check{H})\}$, to a Tannakian functor

$$
\tilde{b r}: \operatorname{Sat}\left(\operatorname{Gr}_{G, \operatorname{Div}_{X}^{1}} ; k\right) \rightarrow \operatorname{Sat}\left(\operatorname{Gr}_{H, \operatorname{Div}_{X}^{1}} ; k\right)
$$

7.2. Good modules. For a geometric point $S=\mathrm{Spa}\left(C, C^{+}\right) \rightarrow \operatorname{Div}_{X}^{1}$, we abbreviate $\operatorname{Gr}_{G, C}:=\operatorname{Gr}_{G, \mathrm{Spa}\left(C, C^{+}\right) / \operatorname{Div}_{X}^{1}}$, and similarly for $\mathrm{Gr}_{H, C}, \mathcal{H}^{\mathrm{ck}} \mathrm{E}_{G, C}$, etc.
Definition 7.2 .1 . We say that an $\mathbb{O}[\Sigma]$-module $M$ is good if it has a finite filtration as $\mathbb{O}[\Sigma]$-modules whose associated graded is a direct sum of (the trivial representation) $\mathbb{O}$ and (the regular representation) $\mathbb{O}[\Sigma]$ with arbitrary multiplicities.

Let $T_{H}$ be a split maximal torus of $H$ over $E^{s}$. Let $\mathcal{F} \in D_{(L+H)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, C} ; \mathbb{O}[\Sigma]\right)^{\text {bd }}$. For each $\mu \in X_{*}\left(T_{H}\right)^{+}$ and $n \in \mathbf{Z}, \mathcal{H}^{n}\left(i_{\mu}^{*} \mathcal{F}\right)$ is a constant sheaf on some $\mathbb{O}[\Sigma]$-module, free over $\mathbb{O}$. We say that $\mathcal{F}$ is good if $\mathcal{H}^{n}\left(i_{\mu}^{*} \mathcal{F}\right)$ is good in the sense of the preceding paragraph for all $\mu \in X_{*}\left(T_{H}\right)^{+}$and all $n \in \mathbf{Z}$.

Let $\mathcal{F} \in\left(D_{(L+G)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, C} ; \mathbb{O}\right)^{\mathrm{bd}}\right)^{B \Sigma}$. We say that $\mathcal{F}$ is good if $\iota^{*} \mathcal{F} \in\left(D_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, C} ; \mathbb{O}\right)^{\mathrm{bd}}\right)^{B \Sigma} \cong D_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, C} ; \mathbb{O}[\Sigma]\right)$ is good in the sense of the preceding paragraph.

Finally, we say that $\mathcal{F} \in\left(D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)^{\mathrm{bd}}\right)^{B \Sigma}$ is good if for all $\bar{s}=\operatorname{Spa}\left(C, C^{+}\right) \rightarrow S$, the *-restriction $\left.\mathcal{F}\right|_{\bar{s}}$ is good in the sense of the preceding paragraph.
Example 7.2.2. The key example is that a permutation representation of $\Sigma$ over $\mathbb{O}$ is good.
Remark 7.2.3. The significance of the definition lies in the fact that if an $\mathbb{O}[\Sigma]$-module $M$ is good, then $\mathrm{T}^{i}(M)$ is concentrated in degree $i \equiv 0(\bmod 2)$. This is because the Tate cohomology of $\mathbb{O}[\Sigma]$ vanishes, and the Tate cohomology of $\mathbb{O}$ lies in even degrees (cf. Example 3.7.1).

To analyze goodness, we will need to use the relationship between the (co)stalks of IC sheaves on $\mathrm{Gr}_{G, C}$ and the weight multiplicities of representations of $\check{G}$, which is documented in more "classical" settings in BF10, Theorem 2.5] and [Zhu17, §5]. Let us formulate the necessary statement.
7.2.1. The Brylinski-Kostant filtration. Recall that $\check{G}$ comes equipped with a pinning. This induces a regular nilpotent element $\check{E} \in \check{\mathfrak{g}}$, which equips any $V \in \operatorname{Rep}(\check{G})$ with the Brylinski-Kostant (increasing) filtration

$$
F_{i} V:=\operatorname{ker}\left(\check{E}^{i+1}: V \rightarrow V\right)
$$

For any $\mu \in X^{*}(\check{T})$, we denote by $V_{\mu}$ the $\mu$-weight space of $V$. Then the above filtration induces a filtration $F_{i}\left(V_{\mu}\right)=V_{\mu} \cap F_{i} V$ on $V_{\mu}$, whose associated graded we denote $\operatorname{gr}_{i}^{F}\left(V_{\mu}\right)$.

Proposition 7.2.4. Let $\mathcal{F} \in \operatorname{Sat}\left(\operatorname{Gr}_{G, C} ; \Lambda\right)$ correspond to $V \in \operatorname{Rep}_{\Lambda}(\check{G})$ under the Geometric Satake equivalence (cf. Example 6.1.3). Then there are natural isomorphisms

$$
\left(i_{\mu}^{*} \mathcal{F}\right)[-\langle 2 \rho, \mu\rangle] \cong \operatorname{gr}_{i}^{F}\left(V_{\mu}\right)
$$

Proof. The statement is equivalent to the analogous one for the Witt vector affine Grassmannian, using [FS21, Corollary VI.6.7] to degenerate from $\mathrm{Gr}_{G, C}$ to $\mathrm{Gr}_{G, S \mathrm{Sd}} \overline{\mathbf{F}}_{q} \cong\left(\mathrm{Gr}_{G}^{\mathrm{Witt}}\right)^{\diamond}$ and then [Sch22, §27] to translate to $\mathrm{Gr}_{G}^{\mathrm{Witt}}$. Then the result appears in the proof of [Zhu21, Proposition 18]: it only requires a small modification of the argument of [Zhu17, §5], replacing the purity argument in RZ15, Lemma 5.8] by the parity argument in the middle of [Zhu17, p.452].

### 7.2.2. The norm of Satake sheaves.

Definition 7.2.5. Given $\mathcal{F} \in \operatorname{Sat}\left(\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right)$, we define

$$
\operatorname{Nm}(\mathcal{F}):=\mathcal{F} \star\left({ }^{\sigma} \mathcal{F}\right) \star \ldots \star\left(\sigma^{\ell-1} \mathcal{F}\right) \in \operatorname{Sat}\left(\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right)^{B \Sigma}
$$

equipped with the $\Sigma$-equivariant structure coming from the commutativity constraint (constructed in 6.1 ) for $\left(\operatorname{Sat}\left(\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right), \star\right)$. Thus Nm induces a functor

$$
\operatorname{Nm}: \operatorname{Sat}\left(\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right) \rightarrow \operatorname{Sat}\left(\operatorname{Gr}_{G, S /\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \Lambda\right)^{B \Sigma}
$$

Note that it is monoidal but neither additive nor $\Lambda$-linear.
Lemma 7.2.6. Let $S$ be a small $v$-stack over $\operatorname{Div}_{X}^{1}$ and let $\mathcal{F} \in \operatorname{Sat}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)$. Then $\operatorname{Nm}(\mathcal{F})$ is good.
Proof. The assertion immediately reduces to the case $S=\mathrm{Spa}\left(C, C^{+}\right)$. Suppose $\mathcal{F}$ corresponds under the Geometric Satake equivalence to $V \in \operatorname{Rep}_{\mathscr{O}}(\check{G})$. Then under the Geometric Satake equivalence, $\operatorname{Nm}(\mathcal{F})$ corresponds to

$$
\mathrm{Nm}(V):=V \otimes\left({ }^{\sigma} V\right) \otimes \ldots \otimes\left(\sigma^{\ell-1} V\right) \in \operatorname{Sat}\left(\operatorname{Gr}_{G, C} ; \mathbb{O}\right)^{B \Sigma}
$$

By Proposition 7.2.4, it suffices to check that for $V \in \operatorname{Rep}_{\mathscr{O}}(\check{G})$ and all $i \in \mathbf{Z}$ that the $\mathbb{O}[\Sigma]$-module $\operatorname{gr}^{i}\left((\mathrm{Nm} V)_{\mu}\right)$ is good, where the associated graded is for the Brylinski-Kostant filtration. Pick a basis for each $V_{\lambda}$ adapted to the filtration $F_{i} V_{\lambda}$. This induces a basis for each $(\mathrm{Nm} V)_{\mu}$ on which $\Sigma$ acts via permutation, and which is adapted to the filtration $F_{i}\left((\operatorname{Nm} V)_{\mu}\right)$. This realizes $\operatorname{gr}_{i}^{F}\left((\mathrm{Nm} V)_{\mu}\right)$ as a permutation representation of $\Sigma$, so each $\operatorname{gr}_{i}^{F}\left((\mathrm{Nm} V)_{\mu}\right)$ is good by Example 7.2.2.
7.2.3. The Smith operation on good parity sheaves preserves parity.

Proposition 7.2.7. Suppose $\mathcal{E} \in \operatorname{Par}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)^{B \Sigma}$ is a relative parity complex (with respect to the dimension pariversity $\dagger_{G}$ ) which is good. Then $\operatorname{Psm}(\mathcal{E}) \in \operatorname{Perf}_{(L+H)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)$ is relative Tate-parity with respect to the induced pariversity $\iota^{*} \dagger G$.
Proof. The assertion immediately reduces to the case $S=\operatorname{Spa}\left(C, C^{+}\right)$. Let $\iota: \operatorname{Gr}_{H, C} \hookrightarrow \operatorname{Gr}_{G, C}$ be the inclusion of $\Sigma$-fixed points. For $\mu \in X_{*}\left(T_{H}\right)^{+} \subset X_{*}(T)^{+}$, we write

$$
\begin{aligned}
& i_{\mu}^{G}: \operatorname{Gr}_{G, C, \mu} \hookrightarrow \operatorname{Gr}_{G, C} \\
& i_{\mu}^{H}: \operatorname{Gr}_{H, C, \mu} \hookrightarrow \operatorname{Gr}_{H, C} \\
& \iota_{\mu}: \operatorname{Gr}_{H, C, \mu} \operatorname{Gr}_{G, C, \mu}
\end{aligned}
$$

Without loss of generality suppose $\mathcal{E}$ is relative even, so we are given that $\left(i_{\mu}^{G}\right)^{?} \mathcal{E}$ has $\mathbb{O}$-free cohomology sheaves concentrated in degrees congruent to $\dagger_{G}(\mu) \bmod 2$, where $? \in\{*,!\}$. We want to show that $\left(i_{\mu}^{H}\right)^{?} \mathbb{T}^{*}\left(\iota^{*} \mathcal{E}\right)$ has Tate-cohomology sheaves supported in degrees congruent to $\dagger_{G}(\mu) \bmod 2$. First we focus on the case $?=*$. Then we have

$$
\left(i_{\mu}^{H}\right)^{*} \mathbb{T}^{*}\left(\iota^{*} \mathcal{E}\right) \cong \mathbb{T}^{*}\left(i_{\mu}^{H}\right)^{*} \iota^{*} \mathcal{E} \cong \mathbb{T}^{*} \iota_{\mu}^{*}\left(i_{\mu}^{G}\right)^{*} \mathcal{E}
$$

By assumption $\mathcal{E}$ is $*$-even on $\operatorname{Gr}_{G, C}$, so $\iota_{\mu}^{*}\left(i_{\mu}^{G}\right)^{*} \mathcal{E}$ has cohomology sheaves being $\mathbb{D}$-free modules in degrees congruent to $\dagger_{G}(\mu) \bmod 2$. Since $\mathcal{E}$ was good by assumption, $\iota_{\mu}^{*}\left(i_{\mu}^{G}\right)^{*} \mathcal{E}$ is good. By Remark 7.2.3. $\mathrm{T}^{j}\left(\iota_{\mu}^{*}\left(i_{\mu}^{G}\right)^{*} \mathcal{E}\right)$ is concentrated in degree $j \equiv \dagger_{G}(\mu)(\bmod 2)$.

For ? =!, we have

$$
\begin{equation*}
\left(i_{\mu}^{H}\right)!\operatorname{Psm}(\mathcal{E})=\left(i_{\mu}^{H}\right)^{!} \mathbb{T}^{*} \iota^{*}(\mathcal{E}) \cong\left(i_{\mu}^{H}\right)^{!} \mathbb{T}^{*} \iota^{!}(\mathcal{E}) \cong \mathbb{T}^{*}\left(i_{\mu}^{H}\right)^{!} \iota^{!}(\mathcal{E}) \cong \mathbb{T}^{*} \iota_{\mu}^{!}\left(i_{\mu}^{G}\right)!\mathcal{E} \tag{7.5}
\end{equation*}
$$

where we used Lemma 3.4 .3 in the second step. By assumption $\mathcal{E}$ is !-even on $\operatorname{Gr}_{G, C}$, so $\left(i_{\mu}^{G}\right)^{!} \mathcal{E}$ has cohomology sheaves being $\mathbb{O}$-free modules in degrees congruent to $\dagger_{G}(\mu) \bmod 2$, and then the same holds for $\iota_{\mu}^{!}\left(i_{\mu}^{G}\right)!\mathcal{E}$ by Lemma 5.4.1. Also, by Verdier duality $\iota_{\mu}^{!}\left(i_{\mu}^{G}\right)!\mathcal{E}$ is good, so Remark 7.2 .3 implies that $\mathrm{T}^{j}\left(\iota_{\mu}^{!}\left(i_{\mu}^{G}\right)!\mathcal{E}\right)$ is concentrated in degree $j \equiv \dagger_{G}(\mu)(\bmod 2)$, as desired.

We denote by

$$
\left(D_{(L+G)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)^{\mathrm{bd}}\right)_{\mathrm{good}}^{B \Sigma} \subset\left(D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)^{\mathrm{bd}}\right)^{B \Sigma}
$$

and

$$
\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)_{\text {good }}^{B \Sigma} \subset \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)_{\text {good }}^{B \Sigma}
$$

the full subcategories of good objects, and we use similar notation for other variants.
7.3. The un-normalized Brauer functor. The pariversity $\dagger_{G}: X_{*}(T) \rightarrow \mathbf{Z} / 2 \mathbf{Z}$ from Example 5.1.7 factors canonically over $\pi_{0}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}}\right)$. Let

$$
\dagger_{H}^{G}:=\left(\iota^{*} \dagger_{G}-\dagger_{H}\right): X_{*}\left(T_{H}\right) \rightarrow \mathbf{Z} / 2 \mathbf{Z}
$$

We denote by

$$
\left[\dagger_{H}^{G}\right]: \operatorname{Perf}_{(L+H)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}} \rightarrow \operatorname{Perf}_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}}
$$

the functor given by shifting by $\dagger_{H}^{G}(c) \in\{0,1\}$ on the connected component $c \subset \operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}}$. We use the same notation for the equivariant version

$$
\left[\dagger_{H}^{G}\right]: \operatorname{Perf}^{\mathrm{ULA}}\left(\mathcal{H}^{\mathrm{ck}}{ }_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}} \rightarrow \operatorname{Perf}^{\mathrm{ULA}}\left(\mathcal{H e k}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}}
$$

and we note that the natural identification $[0] \cong[2]$ on $\operatorname{Perf}^{U L A}\left(\mathcal{H}^{2} \mathrm{ck}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}}$ makes this functor monoidal. By Proposition 7.2.7, the composite functor $\left[\dagger_{H}^{G}\right] \circ$ Psm sends

$$
\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)_{\mathrm{good}}^{B \Sigma} \rightarrow \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{\mathbb{O}}\right)
$$

where parity is with respect to the dimension pariversities (of $G$ on the LHS and $H$ on the RHS).
Definition 7.3.1 (Un-normalized Brauer functor). Assume $\ell>\max \{b(\check{G}), b(\check{H})\}$. With $L$ the lifting functor from $\$ 5.7$, we define the functor $\mathcal{B} r:=L \circ\left[\dagger_{H}^{G}\right] \circ \mathrm{Psm}$ as in the diagram

We regard $\mathcal{B} r$ as a categorification of the un-normalized Brauer homomorphism 7.3.
7.4. The normalized Brauer functor. Recall (cf. 2.7) that for an $\mathbb{O}$-linear abelian category C, we abbreviate

$$
\mathrm{C} \otimes_{\mathbb{O}} k:=\mathrm{C} \otimes_{\mathbb{O}-\mathrm{Mod}}(k-\operatorname{Mod}) .
$$

The construction below is a categorical analogue of $\$ 7.1 .2$
Construction 7.4.1 (Frobenius twist of categories). We summarize [Fen, Construction 4.17]. Let Frob be the $\ell$-power absolute Frobenius of $k$. Given a $k$-linear category C, the Frobenius twist category is $\mathrm{C}^{(\ell)}:=$ $\mathrm{C} \otimes_{k, \text { Frob }} k$. Concretely, it is equivalent to the category which has the same objects as $C$, and morphisms

$$
\operatorname{Hom}_{\mathrm{C}^{(\ell)}}(x, y)=\operatorname{Hom}_{\mathrm{C}}(x, y)^{(\ell)}:=\operatorname{Hom}_{\mathrm{C}}(x, y) \otimes_{k, \operatorname{Frob}} k .
$$

The tautological functor $\mathrm{C} \rightarrow \mathrm{C}^{(\ell)}$ is a Frob-semilinear equivalence.
Suppose we are given a presentation

$$
\begin{equation*}
\mathrm{F}_{0}: \mathrm{C} \cong \mathrm{C}_{0} \otimes_{\mathbf{F}_{\ell}} k \tag{7.7}
\end{equation*}
$$

for some $\mathbf{F}_{\ell}$-linear category $\mathrm{C}_{0}$. Then 7.7 induces another, $k$-linear equivalence $\mathrm{C} \xrightarrow{\sim} \mathrm{C}^{(\ell)}$. Combined with the tautological Frob-semilinear equivalence $C \rightarrow C^{(\ell)}, 7.7$ induces a Frob-semilinear equivalence Frob $_{F_{0}}: C \xrightarrow{\sim} \mathrm{C}$. This factors any Frob-semilinear functor $\mathrm{F}: \mathrm{C} \rightarrow \mathrm{D}$ over $k$-linear functor $\mathrm{F}^{\left(\ell^{-1}\right)}: \mathrm{C} \rightarrow \mathrm{D}$, which we call the linearization of F (with respect to $\mathrm{F}_{0}$ ).
7.4.1. Initial construction. Assume $\ell>\max \{b(\check{G}), b(\check{H})\}$. By Corollary 5.5.5 and Lemma 7.2.6, the functor Nm on parity sheaves factors through $\mathrm{Nm}: \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right) \rightarrow \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)_{\text {good }}^{\Sigma}$. Hence we may consider the composition

$$
\begin{equation*}
\mathcal{B} r \circ \mathrm{Nm}: \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right) \rightarrow \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; k\right) \tag{7.8}
\end{equation*}
$$

This maps to a $k$-linear category, hence factors uniquely through the $k$-linearization of the source, which is identified by the following Lemma.

Lemma 7.4.2. Assume $\ell>\max \{b(\check{G}), b(\check{H})\}$. We have

$$
\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right) \otimes \mathbb{O} \xrightarrow{\sim} \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right) .
$$

Proof. The functor is well-defined by Lemma 5.6.1(1). It is essentially surjective because $\mathbb{O}$-parity sheaves exist for all strata, by Proposition 5.5.4. Finally, Lemma 5.1.11 implies that it is fully faithful, completing the proof.

By Lemma 7.4.2 the functor 7.8 factors uniquely through a functor

$$
b r^{(\ell)}: \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right) \rightarrow \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; k\right)
$$

Note that $b r^{(\ell)}$ is Frob-semilinear. The equivalence

$$
\begin{equation*}
\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right) \cong \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbf{F}_{\ell}\right) \otimes_{\mathbf{F}_{\ell}} k \tag{7.9}
\end{equation*}
$$

furnishes a natural $\mathbf{F}_{\ell \text {-structure on }} \operatorname{Par}_{n}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right)$, so we are in the setup to apply Construction 7.4.1.

Definition 7.4.3. Assume $\ell>\max \{b(\check{G}), b(\check{H})\}$. We define

$$
b r: \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right) \rightarrow \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; k\right)
$$

to be the linearization of $b r^{(\ell)}$.
The functor $b r$ is an approximation to the definition of the normalized Brauer homomorphism (7.4. We still have to extend it to all perverse sheaves, and then descend to $\operatorname{Div}_{X}^{1}$.
Remark 7.4.4. Parallel to (7.4), we have equivalently $b r \cong\left(\mathcal{B} r \circ \mathrm{Nm}^{\left(\ell^{-1}\right)}\right) \otimes_{\mathbb{O}} k$ where $\mathrm{Nm}^{\left(\ell^{-1}\right)}$ is the linearization of Nm .

In 87.6 below, we will prove the following theorem.
Theorem 7.4.5. Assume $\ell>\max \{b(\check{G}), b(\check{H})\}$. The functor br: $\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right) \rightarrow \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; k\right)$ is additive, symmetric monoidal, and compatible with the fiber functor.

Note that the compatibility with the fiber functor implies in particular that $b r$ is exact and faithful.
7.4.2. Extending to abelian envelopes. Assume $S=\mathrm{Spa}\left(C, C^{+}\right)$for the moment. By Theorem 6.2.2, under the Geometric Satake equivalence 6.2 we have

$$
\operatorname{Par}_{\mathrm{n}}^{U L A}\left(\operatorname{Gr}_{G, C} ; k\right) \cong \operatorname{Tilt}_{k}(\check{G}) \quad \text { and } \quad \operatorname{Par}_{\mathrm{n}}^{U L A}\left(\operatorname{Gr}_{H, C} ; k\right) \cong \operatorname{Tilt}_{k}(\check{H})
$$

By CEOP22, Proposition 7.3.1], the abelian envelope of the $\operatorname{Tilt}_{k}(\check{G})$ is $\operatorname{Rep}_{k}(\check{G})$, which corresponds under the Geometric Satake equivalence to $\operatorname{Sat}\left(\mathrm{Gr}_{G, C} ; k\right)$. Therefore the abelian envelope of $\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, C} ; k\right)$ is $\operatorname{Sat}\left(\operatorname{Gr}_{G, C} ; k\right)$. Invoking Theorem 7.4 .5 to see that $b r$ is faithful and exact, the universal property of the abelian envelope gives a unique extension of $b r$ to a functor

$$
\begin{equation*}
b r: \operatorname{Sat}\left(\operatorname{Gr}_{G, C} ; k\right) \rightarrow \operatorname{Sat}\left(\operatorname{Gr}_{H, C} ; k\right) \tag{7.10}
\end{equation*}
$$

Now suppose more generally that $S$ is strictly totally disconnected. For a commutative ring $R$, let $\operatorname{Proj}{ }^{\mathrm{f}}(R)$ be the category of finite projective $R$-modules. Then for $C^{\infty}(|S| ; k)$ the ring of continuous functions on $|S|$ valued in $k$, we have from Example 6.1.3 an equivalence

$$
\operatorname{Sat}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right) \cong \operatorname{Rep}_{k}(\check{G}) \otimes_{k} \operatorname{Proj}^{\mathrm{f}}\left(C^{\infty}(|S| ; k)\right)
$$

Hence tensoring $\sqrt{7.10}$ with $\operatorname{Proj}^{\mathrm{f}}\left(C^{\infty}(|S| ; k)\right)$ gives an extension of $b r$ to the full Satake categories,

which is compatible with base change in $S$.
7.4.3. Descending to $\operatorname{Div}_{X}^{1}$. Recall that $S \mapsto D_{\text {êt }}^{\mathrm{ULA}}\left(\mathcal{H}_{\mathrm{ck}}^{G, S / \operatorname{Div}_{X}^{1}}{ }^{\prime} ; k\right)^{\text {bd }}$ satisfies v-descent, and every locally spatial diamond admits a v-cover by strictly totally disconnected spaces. Since the relative perversity condition is v-local on $S$ by definition, we have a compatible diagram

where we abbreviate "str.t.d." for "strictly totally disconnected". Comparing with the analogous diagram for $H$, this descends the functor $b r$ from 7.11 to a functor

$$
\begin{equation*}
\tilde{b r}: \operatorname{Sat}\left(\operatorname{Gr}_{G, \operatorname{Div}_{X}^{1}} ; k\right) \rightarrow \operatorname{Sat}\left(\operatorname{Gr}_{H, \operatorname{Div}_{X}^{1}} ; k\right) \tag{7.12}
\end{equation*}
$$

We regard $\tilde{b r}$ as the categorification of the normalized Brauer homomorphism (7.4).

Remark 7.4.6. We record for future use the following property of 7.12 , which is arranged by construction: We have a natural isomorphism for all $\mathcal{F} \in \operatorname{Sat}\left(\operatorname{Gr}_{G, \operatorname{Div}_{X}^{1}} ; k\right)$,

$$
\begin{equation*}
\mathbb{T} \widetilde{b r}(\mathcal{F}) \cong\left[\dagger_{H}^{G}\right] \operatorname{Psm}\left(\mathrm{Nm}^{\left(\ell^{-1}\right)}(\mathcal{F})\right) \in D^{\mathrm{ULA}}\left(\mathcal{H}^{\mathrm{Ck}}{ }_{H, \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{k}\right) \tag{7.13}
\end{equation*}
$$

7.5. Compatibility with constant terms. Suppose $G, H$ are split, and $\Sigma$ stabilizes a Borus $(B, T)$. This can always be arranged after a finite cover, by Steinberg's Theorem [Ste68, Theorem 7.5]. Then $\left(B^{\sigma}, T^{\sigma}\right)=:\left(B_{H}, T_{H}\right)$ is a Borus of $H$, according to Lemma 4.2.1. We have a commutative diagram

where the vertical maps are the inclusion of $\sigma$-fixed points (cf. \$4.1) and each square is Cartesian. Any $\mathcal{F} \in D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}$ is monodromic (cf. FS21, Definition IV.6.11] for the definition) for the $\mathbf{G}_{m}$ acting through $2 \rho_{G}: \mathbf{G}_{m} \rightarrow G \subset L^{+} G$. The Constant Term (i.e., hyperbolic localization) functor (for $G$ ), defined in [FS21, Corollary VI.3.5], is the functor

$$
\mathrm{CT}_{B}=\mathrm{R}\left(p_{G}^{+}\right)!\left(q_{G}^{+}\right)^{*}: D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}} \rightarrow D_{\left(L^{+} T\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{T, S / \operatorname{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}}
$$

We have a similar story for $H$ with respect to the Borus $\left(B_{H}, T_{H}\right)$.
Denote by $\left[\operatorname{deg}_{G}\right]$ the function $X_{*}(T) \xrightarrow{\left\langle 2 \rho_{G},-\right\rangle} \mathbf{Z}$, and similarly for $H$. Set

$$
\mathrm{CT}_{B}\left[\operatorname{deg}_{G}\right]:=\bigoplus_{\nu \in X_{*}(T)} \mathrm{R}\left(p_{G}^{+}\right)!i_{\nu!} i_{\nu}^{*}\left(q_{G}^{+}\right)^{*}\left[\left\langle 2 \rho_{G}, \nu\right\rangle\right]
$$

where $i_{\nu}: S_{\nu} \hookrightarrow \operatorname{Gr}_{B, S / \operatorname{Div}_{X}^{1}}$ is the (open-closed) inclusion of the semi-infinite orbit through [ $\nu$ ]; cf. [FS21, $\S$ VI.3] for more about it. Then $\mathrm{CT}_{G}\left[\mathrm{deg}_{G}\right]$ is t-exact and under the Geometric Satake equivalence intertwines with restriction along $\check{T} \rightarrow \check{G}$ by construction [FS21, §VI.11]. There is a completely analogous story for $H$.

Lemma 7.5.1. There is a natural commutative square

$$
\begin{gather*}
D_{\left(L^{+} G\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{\left.G, S / \mathrm{Div}_{X}^{1} ; \Lambda\right)^{\mathrm{bd}} \xrightarrow{\mathrm{Psm}} D_{\left(L^{+} H\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \mathrm{Div}_{X}^{1}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}}} \begin{array}{l}
\downarrow \mathrm{CT}_{B} \\
D_{(L+T)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{T, S / \mathrm{Div}_{X}^{1}} ; \Lambda\right)^{\mathrm{bd}} \xrightarrow{\mathrm{Psm}} D_{\left(L+T_{H}\right)}^{\mathrm{ULA}}\left(\mathrm{Gr}_{T_{H}, S / \mathrm{Div}_{X}^{1}} ; \mathcal{T}_{\Lambda}\right)^{\mathrm{bd}}
\end{array} .\right.
\end{gather*}
$$

Proof. By Lemma 5.2.9 and the $\Sigma$-fixed point calculations in Proposition 4.1.2 and Proposition 4.2.2, Psm interchanges $\left(q_{G}^{+}\right)^{*}$ with $\left(q_{H}^{+}\right)^{*}$; similarly using Proposition 5.2.10. Psm interchanges $\mathrm{R}\left(p_{G}^{+}\right)$! with $\mathrm{R}\left(p_{H}^{+}\right)$!.

Lemma 7.5.2. Assume $\ell>\max \{b(\check{G}), b(\check{H})\}$. There is a natural commutative square

Proof. By construction, it suffices to produce for each strictly totally disconnected $S$ over Div ${ }_{X}^{1}$ a natural (including compatibility with base change in $S$ ) commutative square

$$
\begin{align*}
& \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right) \xrightarrow{b r} \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; k\right) \\
& \downarrow \mathrm{CT}_{B}\left[\operatorname{deg}_{G}\right] \quad \downarrow \mathrm{CT}_{B_{H}}\left[\operatorname{deg}_{H}\right]  \tag{7.16}\\
& \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{T, S / \operatorname{Div}_{X}^{1}} ; k\right) \xrightarrow{b r} \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{T_{H}, S / \operatorname{Div}_{X}^{1}} ; k\right)
\end{align*}
$$

Consider the commutative diagram

The left square commutes because $\mathrm{CT}_{B}[\operatorname{deg} G]$ is symmetric monoidal. The middle square commutes by Lemma 7.5.1. We claim that the right square commutes. To see this, we consider the diagram

The upper and lower caps commute by (5.12). It is immediate from the definition of the modular reduction functor $\mathbb{F}$ that the outer square commutes. In the left square, the horizontal arrows are essentially surjective by Proposition 5.6 .2 and the fact that (under our assumptions on $\ell$ ) all parity sheaves exist in $\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)$ and $\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{T_{H}, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)$, by Theorem 5.7.2 (which is obvious in the latter case). The maps on morphisms are described in $\$ 5.7$, in terms of Lemma 5.3.1. From this we see that the commutativity of the outer square of $(7.18$ implies commutativity of the right square.

Since the right square of 7.18 is the same as that of 7.17 , we have now established that the outer rectangle in 7.17 commutes. Therefore, by definition, the diagram

$$
\begin{aligned}
& \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right) \xrightarrow{b r^{(\ell)}} \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; k\right) \\
& \downarrow \mathrm{CT}_{B}\left[\operatorname{deg}_{G}\right] \quad \downarrow \mathrm{CT}_{B_{H}}\left[\operatorname{deg}_{H}\right] \\
& \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{T, S / \operatorname{Div}_{X}^{1}} ; k\right) \xrightarrow{b r^{(\ell)}} \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{T_{H}, S / \operatorname{Div}_{X}^{1}} ; k\right)
\end{aligned}
$$

commutes. Finally, applying the Frobenius linearization process of Construction 7.4.1 completes the proof for the commutativity of 7.16 .
7.6. The $\sigma$-dual homomorphism. The proof of Theorem 7.4 .5 is completed by combining Proposition 7.6.4 Corollary 7.6.5, and Proposition 7.6.6, which are proved below. Before embarking on these proofs, we draw a few consequences.

By the construction of $\tilde{b r}$, Theorem 7.4.5 implies the following:
Theorem 7.6.1. Assume $\ell>\max \{b(\check{G}), b(\check{H})\}$. Then the functor $\widetilde{b r}: \operatorname{Sat}\left(\operatorname{Gr}_{G, \operatorname{Div}_{X}^{1}} ; k\right) \rightarrow \operatorname{Sat}\left(\operatorname{Gr}_{H, \operatorname{Div}_{X}^{1}} ; k\right)$ is additive, symmetric monoidal, and compatible with the fiber functor.

Recall that

$$
\operatorname{Rep}_{\operatorname{Loc}\left(\operatorname{Div}_{X}^{1} ; \Lambda\right)}(\check{G}) \cong \operatorname{Rep}_{\operatorname{Rep}_{\Lambda}\left(W_{E}\right)}(\check{G}) \cong \operatorname{Rep}_{\Lambda}\left({ }^{L} G\right)
$$

for the $L$-group ${ }^{L} G \cong \check{G} \rtimes W_{E}$. Note that this differs from Langlands' convention for the $L$-group by a cyclotomic twist on root groups, although the difference can be trivialized by choosing a square root of the cyclotomic character; see [FS21] §VI.11] for the precise relation.

Corollary 7.6.2. Assume $\ell>\max \{b(\check{G}), b(\check{H})\}$. Then the functor

$$
\tilde{b r}: \operatorname{Sat}\left(\operatorname{Gr}_{G, \operatorname{Div}_{X}^{1}} ; k\right) \rightarrow \operatorname{Sat}\left(\operatorname{Gr}_{H, \operatorname{Div}_{X}^{1}} ; k\right)
$$

corresponds under the Geometric Satake equivalence to the restriction ${ }^{L} \psi: \operatorname{Rep}\left({ }^{L} G\right) \rightarrow \operatorname{Rep}\left({ }^{L} H\right)$ along some homomorphism ${ }^{L} \psi:{ }^{L} H \rightarrow{ }^{L} G$.
Proof. The existence of ${ }^{L} \psi$ with the stated property follows from the definitions of ${ }^{L} G,{ }^{L} H$ via the Tannakian reconstruction process used in [FS21, Proposition VI.10.2].

Remark 7.6.3. The second main theorem of Treumann-Venkatesh (see [TV16, §1.3]) is the construction of a $\sigma$-dual homomorphism when $G$ is simply connected and $H$ is semisimple, with three possible exceptions when $G$ has type $\mathrm{E}_{6}$. Their proof is based on classification of all possible examples, and then case-by-case analysis of each. By contrast, our construction is completely uniform.

However, our assumption on $\ell$ leaves out many interesting examples in [TV16] which are specific to small primes. This is partly due to the suboptimal hypotheses in Theorem 6.2 .2 , which we believe to be an artefact of the less developed state of geometric representation theory in $p$-adic geometry; for example, we take shortcuts in order to circumvent developing a theory of Soergel bimodules in this setting. It is also partly due to genuine problems with the theory of parity sheaves in very small characteristic; a finer investigation of perverse parity sheaves may allow us to extend our results to all $\ell$. We hope to return to this in future work.

Finally, we recall that Treumann-Venkatesh pointed out TV14, §7.8] that without the simply connected hypotheses a $\sigma$-dual homomorphism need not exist with the "usual" $L$-group defined by Langlands, and they predicted that using instead the " $c$-group" might fix this issue. This prediction is morally consistent with our Theorem 7.6.1 since the $L$-group formed by taking the natural $W_{E}$-action on $\check{G}$ is exactly this $c$-group: see [FS21, VI.11] and [Zhu17, Remark 5.5.11].
7.6.1. Compatibility with fiber functor. The fiber functor on $\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right)\left(\right.$ resp. $\left.\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; k\right)\right)$ is given by relative cohomology over $S$,

$$
\mathcal{F} \mapsto \bigoplus_{i} \mathrm{R}^{i} \pi_{G, S *}(\mathcal{F}) \quad\left(\text { resp. } \mathcal{F} \mapsto \bigoplus_{i} \mathrm{R}^{i} \pi_{H, S *}(\mathcal{F})\right)
$$

where

$$
\pi_{G, S}: \mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} \rightarrow S \quad \text { resp. } \quad \pi_{H, S}: \mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} \rightarrow S
$$

are the natural projections.
Proposition 7.6.4. The functor br is compatible with the fiber functors (cf. (7.24) below).
Proof. Let $I=\operatorname{Gal}\left(\breve{E}^{s} / \breve{E}\right)$ be the inertia subgroup of $E$. For $c \in \pi_{1}(H)_{I}$, there is an open-closed embedding $\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}}(c) \hookrightarrow \operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}}$. For a complex $\mathcal{K} \in \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{T}_{k}\right)$, this induces a decomposition $\mathcal{K} \cong \bigoplus_{c \in \pi_{1}(H)_{I}} \mathcal{K}(c)$. We write

$$
\mathrm{T}^{\dagger_{H}^{G}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{K}\right):=\bigoplus_{c \in \pi_{1}(H)_{I}} \mathrm{~T}^{\dagger_{H}^{G}(c)}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; \mathcal{K}(c)\right)
$$

i.e., we take Tate cohomology in degree $\dagger_{H}^{G}(c)$ on the connected component $c$.

By Proposition 5.2.10 we have a natural isomorphism

$$
\begin{equation*}
\mathrm{T}^{0}\left(\mathrm{R} \pi_{G, S *}(\operatorname{Nm} \mathcal{F})\right) \cong \mathrm{T}^{0}\left(\mathrm{R} \pi_{H, S *}(\operatorname{Psm} \circ \operatorname{Nm} \mathcal{F})\right) \tag{7.19}
\end{equation*}
$$

Then as in Remark 7.4.6 we obtain a natural isomorphism

$$
\begin{equation*}
\mathrm{T}^{0}\left(\mathrm{R} \pi_{H, S *}(\operatorname{Psm} \circ \mathrm{Nm} \mathcal{F})\right) \cong \mathrm{T}^{\dagger}{ }_{H}^{G}\left(\mathrm{R} \pi_{H, S *}\left(\mathbb{T} \circ b r^{(\ell)}(\mathcal{F})\right)\right) \tag{7.20}
\end{equation*}
$$

By Example 3.7.4, we have

$$
\begin{equation*}
\mathrm{T}^{\dagger}{ }_{H}^{G}\left(\mathrm{R} \pi_{H, S *}\left(\mathbb{T} \circ b r^{(\ell)}(\mathcal{F})\right)\right) \cong \bigoplus_{n \in \mathbf{Z}} \mathrm{R}^{n} \pi_{H, S *}\left(b r^{(\ell)}(\mathcal{F})\right) \tag{7.21}
\end{equation*}
$$

Below we abbreviate the fiber functor on $\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right)$ as

$$
\mathrm{F}^{G}:=\bigoplus_{n \in \mathbf{Z}} \mathrm{R}^{n} \pi_{G, S *}: \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right) \rightarrow \operatorname{Loc}(S ; k)
$$

and similarly for $H$. Putting together equations 7.19, 7.20, and 7.21, we have produced a natural isomorphism of $k$-semilinear functors $\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right) \rightarrow \operatorname{Loc}(S ; k)$ :

$$
\begin{equation*}
\mathrm{T}^{0}\left(\mathrm{~F}^{G}(\mathrm{Nm} \mathcal{F})\right) \cong \mathrm{F}^{H}\left(b r^{(\ell)}(\mathcal{F})\right) \tag{7.22}
\end{equation*}
$$

By definition, we have

$$
\mathrm{F}^{G}(\mathrm{Nm}(\mathcal{F})) \cong\left(\mathrm{F}^{G}(\mathcal{F})\right) \otimes\left({ }^{\sigma} \mathrm{F}^{G}(\mathcal{F})\right) \otimes \ldots \otimes\left(\sigma^{\ell-1} \mathrm{~F}^{G}(\mathcal{F})\right) \in \operatorname{Loc}(S ; k)
$$

with $\sigma$ acting by cyclic rotation of the factors, so we have (cf. Example 3.7.2) a natural isomorphism

$$
\begin{equation*}
\mathrm{T}^{0}\left(\mathrm{~F}^{G}(\operatorname{Nm}(\mathcal{F}))\right) \cong \mathrm{F}^{G}(\mathcal{F})^{(\ell)} \tag{7.23}
\end{equation*}
$$

Putting $\sqrt{7.23}$ into 7.22 , we obtain the commutative diagram

$$
\begin{gathered}
\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right) \xrightarrow{b r^{(\ell)}} \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; k\right) \\
\operatorname{DF}^{\left(\mathrm{F}^{G}\right)^{(\ell)} \downarrow} \underset{\downarrow}{\operatorname{Loc}(S: k)} \xrightarrow{\operatorname{Loc}(S: k)}
\end{gathered}
$$

Then applying linearization with respect to the $\mathbf{F}_{\ell}$-structure 7.9 gives the desired commutative diagram

$$
\begin{gather*}
\operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right) \stackrel{b r}{\longrightarrow} \operatorname{Par}_{\mathrm{n}}^{\mathrm{ULA}}\left(\mathrm{Gr}_{\left.H, S / \operatorname{Div}_{X}^{1} ; k\right)}\right. \\
\mathrm{F}^{G} \downarrow  \tag{7.24}\\
\operatorname{Loc}(S ; k) \xrightarrow{\mid \mathrm{F}^{H}} \\
\operatorname{Loc}(S ; k)
\end{gather*}
$$

Corollary 7.6.5. The functor br is additive.
Proof. The additivity can be checked after applying the fiber functor, since the latter is faithful. Then conclude using (7.24) and the additivity of the fiber functor $\mathrm{F}^{G}$.
7.6.2. Symmetric monoidality. We complete the proof of Theorem 7.4.5 with the Proposition below.

Proposition 7.6.6. The functor br promotes to a symmetric monoidal functor.
Proof. First we promote $b r$ to a monoidal functor. For this it suffices to produce, naturally in $\mathcal{F}$ and $\mathcal{G}$, an isomorphism

$$
\begin{equation*}
\mathcal{B} r\left(\operatorname{Nm}^{\left(\ell^{-1}\right)}(\mathcal{F} \star \mathcal{G})\right) \cong \mathcal{B} r\left(\operatorname{Nm}^{\left(\ell^{-1}\right)}(\mathcal{F})\right) \star \mathcal{B} r\left(\operatorname{Nm}^{\left(\ell^{-1}\right)} \mathcal{G}\right) \tag{7.25}
\end{equation*}
$$

Since $\mathrm{Nm}^{\left(\ell^{-1}\right)}$ has an evident symmetric monoidal structure, we rename $\mathcal{F}^{\prime}:=\mathrm{Nm}^{\left(\ell^{-1}\right)} \mathcal{F}$ and $\mathcal{G}^{\prime}:=$ $\mathrm{Nm}{ }^{\left(\ell^{-1}\right)} \mathcal{G}$, and aim to produce a natural isomorphism

$$
\mathcal{B} r\left(\mathcal{F}^{\prime} \star \mathcal{G}^{\prime}\right) \cong \mathcal{B} r\left(\mathcal{F}^{\prime}\right) \star \mathcal{B} r\left(\mathcal{G}^{\prime}\right)
$$

Indeed, we have

$$
\begin{aligned}
\mathcal{B} r\left(\mathcal{F}^{\prime} \star \mathcal{G}^{\prime}\right) & =L \circ\left[\dagger_{H}^{G}\right] \operatorname{Psm}\left(m_{!}\left(p_{0}^{*} \mathcal{F}^{\prime} \otimes p_{1}^{*} \mathcal{G}^{\prime}\right)\right) \\
\text { Lemma } 5.2 .9+\text { Proposition } 5.2 .10 & \cong L \circ\left[\dagger_{H}^{G}\right] \circ m_{!}\left(p_{0}^{*}\left(\operatorname{Psm} \mathcal{F}^{\prime}\right) \otimes p_{1}^{*}\left(\operatorname{Psm} \mathcal{G}^{\prime}\right)\right) \\
& =L \circ\left[\dagger_{H}^{G}\right]\left(\operatorname{Psm} \mathcal{F}^{\prime} \star \operatorname{Psm} \mathcal{G}^{\prime}\right) \\
{[0] \cong[2] \Longrightarrow } & =L\left(\left(\left[\dagger_{H}^{G}\right] \operatorname{Psm} \mathcal{F}^{\prime}\right) \star\left(\left[\dagger_{H}^{G}\right] \operatorname{Psm} \mathcal{G}^{\prime}\right)\right) \\
\text { Lemma } 5.7 .5 & \cong L\left(\left[\dagger_{H}^{G}\right] \operatorname{Psm} \mathcal{F}^{\prime}\right) \star L\left(\left[\dagger_{H}^{G}\right] \operatorname{Psm} \mathcal{G}^{\prime}\right) \\
& =\mathcal{B} r\left(\mathcal{F}^{\prime}\right) \star \mathcal{B} r\left(\mathcal{G}^{\prime}\right) .
\end{aligned}
$$

This furnishes the monoidal structure (7.25).
Next we need to check that the monoidal functor br has the property of being symmetric monoidal. For this purpose, we may make a finite base change along $S$ to reduce to the case where $G$ is split, and has a Borus $(B, T)$. By Lemma 4.2.1, $\left(B^{\sigma}, T^{\sigma}\right)=:\left(B_{H}, T_{H}\right)$ is a Borus of $H$. Since $\mathrm{CT}_{B_{H}}$ is faithful, it suffices to
check the symmetric monoidality property after applying $\mathrm{CT}_{B_{H}}$. Using Lemma 7.5 .2 , we are then reduced to the case where $G$ and $H$ are both tori. In this case, we have

$$
\mathrm{Gr}_{T, S / \operatorname{Div}_{X}^{1}}=\coprod_{X_{*}(T)} S \quad \text { and } \quad \mathrm{Gr}_{T_{H}, S / \operatorname{Div}_{X}^{1}}=\coprod_{X_{*}\left(T_{H}\right)} S
$$

and the commutativity constraints for $G, H$ comes from convolution on $X_{*}(T), X_{*}\left(T_{H}\right)$ respectively. Then the symmetric monoidality is clear from inspection.

The proof of Proposition 7.6 .6 gives the following information about the induced map of tori.
Corollary 7.6.7. Let $\check{T}_{H}, \check{T}$ be the canonical maximal tori in $\check{H}, \check{G}$, respectively. The restriction $\check{\psi}: \check{T}_{H} \rightarrow \check{T}$ corresponds to the map $X^{*}(\check{T}) \rightarrow X^{*}\left(\check{T}_{H}\right)=X^{*}(\check{T})^{\sigma}$ given by applying $N=\left(1+\sigma+\ldots+\sigma^{\ell-1}\right)$.
7.7. Multiple legs. For a finite non-empty set $I$, we abbreviate $\operatorname{Sat}_{G}^{I}(k):=\operatorname{Sat}\left(\operatorname{Gr}_{G,\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; k\right)$.

Theorem 7.7.1. There are Tannakian functors

$$
\widetilde{b r}^{I}: \operatorname{Sat}_{G}^{I}(k) \rightarrow \operatorname{Sat}_{H}^{I}(k)
$$

for each non-empty finite set $I$, with the following properties.
(1) Under the Geometric Satake equivalence (6.1) of Fargues-Scholze, $\widetilde{b r}^{I}$ corresponds to the restriction ${ }^{L} \psi^{*}: \operatorname{Rep}_{k}\left({ }^{L} G\right)^{\otimes I} \rightarrow \operatorname{Rep}_{k}\left({ }^{L} H\right)^{\otimes I}$ induced by the $\sigma$-dual homomorphism ${ }^{L} \psi:{ }^{L} H \rightarrow{ }^{L} G$ from Corollary 7.6.2. (In particular, $\widetilde{b r}^{\{1\}}$ agress with the $\widetilde{b r}$ from (7.12).)
(2) (Naturality in I) For any map of non-empty finite sets $\zeta: I \rightarrow J$, there is a commutative square

such that the implicit natural isomorphisms are compatible with compositions $I \rightarrow J \rightarrow K$.
(3) For $\mathcal{F} \in \operatorname{Sat}_{G}^{I}(k)$, there are natural isomorphisms

$$
\mathbb{T} \tilde{b r}^{I}(\mathcal{F}) \cong\left[\dagger_{H}^{G}\right] \operatorname{Psm}\left(\mathrm{Nm}^{\left(\ell^{-1}\right)} \mathcal{F}\right) \in D^{\mathrm{ULA}}\left(\mathcal{H}^{\left(\mathrm{ck}_{H,\left(\operatorname{Div}_{X}^{1}\right)^{I}} ; \mathcal{T}_{k}\right)^{\mathrm{bd}} .}\right.
$$

compatible with any map of finite sets $\zeta: I \rightarrow J$ as in (2).
Proof. Write $I=\bigsqcup_{i \in I}\{i\}$. We bootstrap from the case $|I|=1$ using the convolution Hecke stack

$$
\widetilde{\mathcal{H} c k}_{G}^{I}:=\mathcal{H}^{\operatorname{ck}_{G}^{I}}{ }_{G}^{; i\}_{i \in I}} \rightarrow\left(\operatorname{Div}_{X}^{1}\right)^{I}
$$

defined in [FS21, p. 226]. We have projection maps $p_{i}: \widetilde{\mathcal{H c k}}_{G}^{I} \rightarrow \widetilde{\mathcal{H} c k}_{G, \operatorname{Div}_{X}^{1}}^{\{i\}}$ for each $i \in I$, as well as a convolution map $m: \widetilde{\mathcal{H} c k}_{G}^{I} \rightarrow \mathcal{H}^{I} k_{G,\left(\operatorname{Div}_{X}^{1}\right)^{I}}$. The map

$$
\left(\mathcal{K}_{i}\right)_{i \in I} \mapsto R m_{!}\left(\otimes_{i \in I} p_{i}^{*} \mathcal{K}_{i}\right) \in \operatorname{Sat}_{G}^{I}(k)
$$

induces an equivalence

$$
\operatorname{conv}: \operatorname{Sat}\left(\operatorname{Gr}_{G, \operatorname{Div}_{X}^{1}}\right)^{\otimes I} \xrightarrow{\sim} \operatorname{Sat}_{G}^{I}(k) .
$$

The same considerations apply to $H$. We define $\widetilde{b r}^{I}: \operatorname{Sat}_{G}^{I}(k) \rightarrow \operatorname{Sat}_{H}^{I}(k)$ by the commutative diagram

Then property (1) follows from the $|I|=1$ case, which was arranged in Corollary 7.6.2, and Tannakian reconstruction [FS21, §11].

For property (2), recall that the fusion map $\operatorname{Sat}_{G}^{I}(k) \rightarrow \operatorname{Sat}_{G}^{J}(k)$ is arranged in [FS21, §VI.9.4] so that under the identifications in the commutative diagram

it corresponds to

$$
\star_{i \in I} \mathcal{F}_{i} \mapsto \otimes_{j \in J}\left(\star_{i \in \zeta^{-1}(j)} \mathcal{F}_{j}\right)
$$

in the top row. Hence the compatibility of $\widetilde{b r}^{I}$ in (2) is equivalent to the symmetric monoidality of $\widetilde{b r}$ with respect to the fusion product, which was established in Theorem 7.6.1.

Property (3) is arranged by construction for $I=\{1\}$ : see 7.13 . For $|I|>1$, we consider the diagram

The outermost rectangle commutes by definition of $\widetilde{b r}^{I}$. The top cap is the $I$ th tensor power of the case $|I|=1$, so it commutes. The right square commutes by compatibility of $\mathbb{T}$ with pushforward and pullback. The left square commutes by (symmetric) monoidality of Nm, compatibility of Psm with pushforward and pullback ( $\$ 5.2 .3$ ), and monoidality of $\left[\dagger_{H}^{G}\right]$. Hence the bottom cap commutes, which gives (3) for general $I$.

## 8. Tate cohomology of moduli of local shtukas

In this section we will integrate the Brauer functor into the construction of the Fargues-Scholze correspondence 1.2 for $H$ and for $G$, in order to deduce information about functoriality.

In $\$ 8.1$ - $\$ 8.4$ we review a construction of the Fargues-Scholze correspondence, which resembles a local version of the work of Vincent Lafforgue Laf18 in the global setting, but (amazingly!) applies equally well in mixed characteristic. Our starting point is the moduli space of local shtukas $\operatorname{Sht}_{(G, b, I), K}$, defined from the input data of a reductive group $G / E$, an element $b$ in the "Kottwitz set" $B(G)$, a finite non-empty set $I$, and a compact open subgroup $K \subset G(E)$. A generalization of the Grothendieck-Messing period map gives an étale morphism from $\operatorname{Sht}_{(G, b, I), K}$ to a "twisted" version of the Beilinson-Drinfeld affine Grassmannian $\mathrm{Gr}_{G, \prod_{i \in I} \operatorname{spd} \check{E}}^{\mathrm{tw}}$. By pulling back sheaves along this morphism, the Geometric Satake equivalence of FarguesScholze supplies a functor from $\operatorname{Rep}_{k}\left(\left({ }^{L} G\right)^{I}\right)$ to sheaves on $\operatorname{Sht}_{(G, b, I), K}$, which are "compatible with fusion" in a suitable sense. According to V. Lafforgue's paradigm, such a collection of functors (compatible with fusion) gives rise to commuting excursion operators on the cohomology of $\operatorname{Sht}_{(G, b, I), K}$, whose simultaneous generalized eigenvalues correspond naturally to semisimple Galois representations.

To study functoriality, we link the processes outlined in the preceding paragraph for $G$ and for $H$ using the Brauer functor from $\$ 7$. (The reader may find it helpful to consult Figure 2 again.) Thanks to the calculations in $\S 4$ we may realize $\operatorname{Sht}_{\left(H, b^{\prime}, I\right), \iota^{*} K}$ as (an open-closed subset of) the $\Sigma$-fixed points of $\operatorname{Sht}_{(G, b, I), K}$, and the Brauer functor $\widetilde{b r}^{I}$ gives a geometric link between the sheaves on $\operatorname{Sht}_{(G, b, I), K}$ indexed by $V \in \operatorname{Rep}_{k}\left(\left({ }^{L} G\right)^{I}\right)$ and the sheaves on $\operatorname{Sht}_{\left(H, b^{\prime}, I\right), \iota^{*} K}$ indexed by ${ }^{L} \psi^{*}(V)$. We feed this link into equivariant localization for Tate cohomology, which is part of the formalism developed in $\$ 3$. In $\$ 8.5$ we define and study excursion operators
on Tate cohomology of the moduli spaces of local shtukas. Then in 8.6 we extract functoriality relations between excursion operators for $\operatorname{Sht}_{(G, b, I), K}$ and for $\operatorname{Sht}_{\left(H, b^{\prime}, I\right), \iota^{*} K}$.
8.1. Moduli spaces of local shtukas. The definitions of local shtukas in $p$-adic geometry are developed in Scholze's Berkeley Lectures on $p$-adic geometry, especially [SW20, Lecture XXIII]. Properties of the cohomology of their moduli spaces are established in [FS21, §IX.3]. We recall some relevant aspects here.
8.1.1. Setup. Recall that $G$ is a reductive group over $E$. For each finite set $I, b \in B(G)$, and compact open subgroup $K<G(E)$, we have a moduli space of local shtukas $\operatorname{Sht}_{(G, b, I), K}$. By [SW20, Theorem 23.1.4], it is an inductive limit of locally spatial diamonds with finite cohomological dimension along a countable index set. Furthermore, there is an action of $G_{b}(E)$ on $\operatorname{Sht}_{(G, b, I), K}$.

The space $\operatorname{Sht}_{(G, b, I), K}$ comes equipped with "leg" maps

$$
f_{K}: \operatorname{Sht}_{(G, b, I), K} \rightarrow \prod_{i \in I} \operatorname{Spd} \breve{E}
$$

which are partially proper and ind-shriekable, and Grothendieck-Messing period maps

$$
\pi_{K}: \operatorname{Sht}_{(G, b, I), K} \rightarrow \operatorname{Gr}_{G, \prod_{i \in I} \operatorname{Spd} \breve{E}}
$$

which are étale.
8.1.2. Satake sheaves. As in [FS21, §IX], we choose a square root of the cyclotomic character $W_{E} \rightarrow k^{\times}$ in order to trivialize the cyclotomic twist in the Geometric Satake equivalence, giving a $W_{E}$-equivariant isomorphism $\check{G} \cong \widehat{G}$.

Let $Q$ be a finite quotient of $W_{E}$ over which the action on $\widehat{G}$-factors. For any finite set $I$ and $W \in$ $\operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right)$, the Geometric Satake equivalence gives a relative perverse sheaf $\mathcal{S}_{W}$ on $\operatorname{Gr}_{G, \prod_{i \in I} \operatorname{spd} \breve{E}}(\mathrm{cf}$. [FS21, §I.9, §IX.3]) which we pull back via $\pi_{K}^{*}$ to $\operatorname{Sht}_{(G, b, I), K}$, and we also denote the resulting complex by $\mathcal{S}_{W} \in D_{\text {êt }}^{b}\left(\operatorname{Sht}_{(G, b, I), K} ; k\right)$.
8.1.3. Cohomology of moduli spaces of local shtukas. By [FS21, Corollary I.7.3, Proposition IX.3.2], we may regard

$$
\begin{equation*}
\mathrm{R} f_{K!} \mathcal{S}_{W} \in D\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G_{b}(E)\right)^{B} \prod_{i \in I} W_{E} \tag{8.1}
\end{equation*}
$$

as a (derived) representation of $G_{b}(E)$ with a commuting action of $\prod_{i \in I} W_{E}$. To demystify this a bit: the $G_{b}(E)$-action on cohomology is induced by the $G_{b}(E)$-action on the space $\operatorname{Sht}_{(G, b, I), K}$, and the $\prod_{i \in I} W_{E^{-}}$ action comes from a natural descent (using an interpretation via Hecke operators) of $\mathrm{R} f_{K!} \mathcal{S}_{W}$ from $\prod_{i \in I} \operatorname{Spd} \breve{E}$ to $\prod_{i \in I}[\operatorname{Spd} \breve{E} / \varphi] \cong \prod_{i \in I}\left[\operatorname{Spd} C / W_{E}\right]$.

Example 8.1.1. For $W=\mathbb{1}$ the trivial representation, $\operatorname{Sht}_{(G, b, I), K}$ is only non-empty for $b=1_{G}$. In this case, $\mathrm{R} f_{K!} \mathcal{S}_{\mathbb{1}}$ is c- $\operatorname{Ind}{ }_{K}^{G(E)}(k)$ with the obvious $G(E)$-action and the trivial $W_{E}$-action.

The functor

$$
\operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right) \rightarrow D\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G_{b}(E)\right)^{B} \prod_{i \in I} W_{E}
$$

sending $\mathcal{S}_{W} \mapsto \mathrm{R} f_{K!} \mathcal{S}_{W}$ satisfies the following fusion compatibility. Any map of finite non-empty sets $\zeta: I \rightarrow J$ induces a map $\left({ }^{L} G\right)^{J} \rightarrow\left({ }^{L} G\right)^{I}$. Let $\operatorname{Res}_{\zeta}: \operatorname{Rep}_{k}\left(\left({ }^{L} G\right)^{I}\right) \rightarrow \operatorname{Rep}_{k}\left(\left({ }^{L} G\right)^{J}\right)$ be the restriction functor along this map. By construction, Geometric Satake is arranged so that the corresponding functor $\operatorname{Sat}_{G}^{I}(k) \rightarrow \operatorname{Sat}_{G}^{J}(k)$ is the fusion product. We have commutative diagrams

The Geometric Satake equivalence is constructed in [FS21, §VI] so that naturally in $W \in \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right)$, one has $\left.\mathcal{S}_{W}\right|_{\operatorname{Gr}_{G, \Pi_{j \in J} \mathrm{Spd}_{\check{E}}} \cong \mathcal{S}_{\operatorname{Res}_{\zeta} W} \text {, compatibly under compositions of finite sets. This induces a natural }}$ isomorphism

$$
\begin{equation*}
\mathrm{R} f_{K!} \mathcal{S}_{W} \cong \mathrm{R} f_{K!} \mathcal{S}_{\operatorname{Res}_{\zeta}(W)} \tag{8.2}
\end{equation*}
$$

of functors $\operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right) \rightarrow D\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G_{b}(E)\right)^{B} \prod_{j \in J} W_{E}$. Moreover, the natural isomorphism 8.2 under compositions of maps of finite sets.
8.2. Excursion algebra. An excursion datum for $\widehat{G}$ (over $k$ ) FS21, Definition VIII.4.2] is a tuple $\mathcal{D}=$ $\left(I, V, \alpha, \beta,\left(\gamma_{i}\right)_{i \in I}\right)$ where:

- $I$ is a finite set and $\gamma_{i} \in W_{E}$ for each $i \in I$,
- $V \in \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right)$ for varying $Q$, and $\left.\mathbb{1} \xrightarrow{\alpha} V\right|_{\widehat{G}}$ and $\left.V\right|_{\widehat{G}} \xrightarrow{\beta} \mathbb{1}$ are maps of $\widehat{G}$-representations.

The excursion algebra $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ is the $k$-algebra on generator $S_{\mathcal{D}}$ for each excursion datum $\mathcal{D}$, with relations as in [Fen, §2.4]. Another definition appears in [FS21, Definition VIII.3.4].

An L-parameter (with coefficients in $k$ ) is a class in $\mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)$, or equivalently a section $W_{E} \rightarrow$ $\widehat{G}(k) \rtimes W_{E}$ up to $\widehat{G}(k)$-conjugation. An $L$-parameter is semisimple if whenever it factors through a parabolic ${ }^{L} P(k) \subset{ }^{L} G(k)$, it also factors through a Levi ${ }^{L} M(k) \subset{ }^{L} P(k)$ [FS21, Definition VIII.3.1].

Combining [FS21, Proposition VIII.3.8] and the statement above [FS21, Definition VIII.3.4] that the natural map from $\operatorname{Exc}\left(W_{E}, \widehat{G}\right)$ to the spectral Bernstein center $\mathcal{O}\left(Z^{1}\left(W_{E}, \widehat{G}\right)\right)^{\widehat{G}}$ is a universal homeomorphism, we obtain a canonical bijection between

$$
\left\{\text { characters } \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right) \rightarrow k\right\} \longleftrightarrow\left\{\text { semisimple } L \text {-parameters } \rho \in \mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)\right\}
$$

Suppose we are given a homomorphism ${ }^{L} \psi:{ }^{L} H \rightarrow{ }^{L} G$. Then for any excursion datum $\mathcal{D}=\left(I, V, \alpha, \beta,\left(\gamma_{i}\right)_{i \in I}\right)$ for $\widehat{G}$, we define

$$
{ }^{L} \psi^{*}(\mathcal{D}):=\left(I,{ }^{L} \psi^{*}(V),{ }^{L} \psi^{*}(\alpha),{ }^{L} \psi^{*}(\beta),\left(\gamma_{i}\right)_{i \in I}\right)
$$

as an excursion datum for $\widehat{H}$. The map $S_{\mathcal{D}} \mapsto S_{L^{*}(\mathcal{D})}$ defines a homomorphism

$$
\begin{equation*}
{ }^{L} \psi^{*}: \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right) \rightarrow \operatorname{Exc}_{k}\left(W_{E}, \widehat{H}\right) \tag{8.3}
\end{equation*}
$$

On spectra, it sends (the point corresponding to) a semisimple $L$-parameter $\rho \in \mathrm{H}^{1}\left(W_{E} ; \widehat{H}(k)\right)$ to (the point corresponding to) the semisimple $L$-parameter ${ }^{L} \psi \circ \rho \in \mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)$.
8.3. The Bernstein center. Recall that in (7.1) we defined the Hecke algebra $\mathscr{H}(G, K ; \Lambda)$ for a compact open subgroup $K \subset G(E)$. We let $\mathfrak{Z}(G, K ; \Lambda):=Z(\mathscr{H}(G, K ; \Lambda))$ be the center of $\mathscr{H}(G, K ; \Lambda)$.

If $K \subset K^{\prime}$ have prime-to- $\ell$ pro-order (e.g., this will be true as long as they are sufficiently small), then convolution with $\mathbb{1}_{K^{\prime}}$ gives a homomorphism $\mathfrak{Z}(G, K ; \Lambda) \rightarrow \mathfrak{Z}\left(G, K^{\prime} ; \Lambda\right)$. The Bernstein center of $G$ (with coefficients in $\Lambda$ ) is

$$
\mathfrak{Z}(G ; \Lambda):=\lim _{\overleftarrow{K}} \mathfrak{Z}(G, K ; \Lambda),
$$

where the transition maps are as above, and the inverse limit is taken over $K$ with prime-to- $\ell$ pro-order.
If $\Lambda=k$, we abbreviate $\mathscr{H}(G, K):=\mathscr{H}(G, K ; k), \mathfrak{Z}(G, K):=\mathfrak{Z}(G, K ; k)$, and $\mathfrak{Z}(G):=\mathfrak{Z}(G ; k)$.
The Bernstein center $\mathfrak{Z}(G)$ may also be identified with the ring of endomorphisms of the identity functor of the category $\operatorname{Rep}_{k}^{\mathrm{sm}}(G(E))$. In particular, any irreducible admissible representation $\Pi$ of $G(E)$ over $k$ induces a character of $\mathfrak{Z}(G)$.
8.4. Review of Fargues-Scholze correspondence. Fargues-Scholze construct in [FS21] a $k$-algebra homomorphism

$$
\begin{equation*}
\mathrm{FS}_{G}: \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right) \rightarrow \mathfrak{Z}(G ; k) \tag{8.4}
\end{equation*}
$$

Via (8.4), $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ acts through a character on any irreducible admissible representation $\Pi \in \operatorname{Rep}_{k}^{\mathrm{sm}}(G(E))$, and the corresponding semisimple $L$-parameter is denoted $\rho_{\Pi} \in \mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)$.

We present the construction of (8.4) on [FS21, p.36]. Fix $b:=1_{G} \in B(G)$. Let

$$
\bar{x}: \operatorname{Spd} \widehat{\widehat{E}} \rightarrow \prod_{i=1}^{n} \operatorname{Spd} \breve{E}
$$

be the geometric diagonal, and $f_{K}^{\Delta}: \operatorname{Sht}_{\left(G, 1_{G}, I\right), K}^{\Delta} \rightarrow \operatorname{Spd} \widehat{\bar{E}}$ be the base change of $f_{K}$ along $\bar{x}$.
Let $K \subset G(E)$ be a compact open subgroup. Recall from Example 8.1.1 that the underlying $G(E)$ representation of $\operatorname{R} f_{K!}^{\Delta} \mathcal{S}_{\mathbb{1}}$ is $\mathrm{c}-\operatorname{Ind}_{K}^{G(E)} k$. Hence for each excursion datum $\mathcal{D}=\left(I, V, \alpha, \beta,\left(\gamma_{i}\right)_{i \in i}\right)$ we have a composition

(in the middle step we used (8.1) to obtain an action of $\prod_{i \in I} W_{E}$ on $\left.\left(\mathrm{R} f_{K!} \mathcal{S}_{V}\right)_{\bar{x}}\right)$ which defines an element $\mathrm{FS}_{G}\left(S_{\mathcal{D}}\right) \in \operatorname{End}_{G(E)}\left(\mathrm{c}-\operatorname{Ind}_{K}^{G(E)} k, \mathrm{c}-\operatorname{Ind}_{K}^{G(E)} k\right) \cong \mathfrak{Z}(G, K)$. As $K$ varies, these elements are compatible under convolution, hence assemble to an element of $\mathfrak{Z}(G)$. The map 8.4 sends $S_{\mathcal{D}}$ to this element of $\mathfrak{Z}(G)$.
8.5. Excursion operators on Tate cohomology. Recall the notion of Tate cohomology from 3.7 We will now study excursion operators on the Tate cohomology of $\operatorname{Sht}_{(G, b, I), K}$.
8.5.1. Tate cohomology of moduli of shtukas. Recall that $G$ has a given action of $\Sigma$. Assume that the level structure $K \subset G(E)$ is $\Sigma$-invariant, and $b \in B(G)$ is $\Sigma$-fixed. Then there is an induced $\Sigma$-action on Sht $_{(G, b, I), K}$.

The given action of $\Sigma$ on $G$ induces an action $V \mapsto{ }^{\sigma} V$ of $\Sigma$ on $\operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right)$. Suppose we have a $\Sigma$-equivariant representation $W \in \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right)^{B \Sigma}$. Then $\mathcal{S}_{W}$ has the structure of a $\Sigma$-equivariant sheaf on $\operatorname{Sht}_{(G, b, I), K}$. Then we have, using (8.1),

$$
\mathrm{R} f_{K!} \mathcal{S}_{W} \in D\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G_{b}(E)\right)^{B\left(\prod_{i \in I} W_{E} \rtimes \Sigma\right)}
$$

Hence we can form the $j$ th Tate cohomology of $\mathrm{R} f_{K!} \mathcal{S}_{W}$ (for $j \in \mathbf{Z} / 2 \mathbf{Z}$ ), which we denote

$$
\begin{equation*}
\mathrm{T}^{j}\left(\operatorname{Sht}_{(G, b, I), K} ; W\right):=\mathrm{T}^{j}\left(\mathrm{R}_{K!} \mathcal{S}_{W}\right) \in D\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G_{b}^{\sigma}(E)\right)^{B} \prod_{i \in I} W_{E} \tag{8.6}
\end{equation*}
$$

as we will want to record the dependence on $G, b, I$.
Example 8.5.1. For $V=\mathbb{1}$, the trivial representation, $\operatorname{Sht}_{(G, b, I), K}$ is only non-empty for $b=1_{G}$. In that case, we have (cf. Example 8.1.1)

$$
\mathrm{T}^{j}\left(\operatorname{Sht}_{\left(G, 1_{G}, I\right), K} ; \mathbb{1}\right) \cong \mathrm{T}^{j}\left(\mathrm{c}-\operatorname{-nd}_{K}^{G(E)} k\right) \in \operatorname{Rep}_{k}^{\mathrm{sm}}(H(E))
$$

A similar story applies to $H$. Note that $\Sigma$ acts trivially on $\operatorname{Sht}_{(H, b, I), K}$, so if $\Sigma$ acts trivially on $W \in$ $\operatorname{Rep}_{k}\left((\widehat{H} \rtimes Q)^{I}\right)$, then by Example 3.7.4 and Example 3.7.1, we have for each $j \in \mathbf{Z} / 2 \mathbf{Z}$ a natural isomorpism

$$
\begin{equation*}
\mathrm{T}^{j}\left(\operatorname{Sht}_{(H, b, I), K} ; W\right) \cong \bigoplus_{n \in \mathbf{Z}} \mathrm{H}^{n}\left(\mathrm{R} f_{K!} \mathcal{S}_{W}\right)=\mathrm{H}^{*}\left(\mathrm{R} f_{K!} \mathcal{S}_{W}\right) \tag{8.7}
\end{equation*}
$$

8.5.2. Excursion action. The $\Sigma$ action on $G$ induces a $\Sigma$-action on $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ by transport of structure. Concretely, $\Sigma$ acts on excursion data by

$$
\sigma \cdot\left(I, V, \alpha, \beta,\left(\gamma_{i}\right)_{i \in I}\right)=\left(I,{ }^{\sigma} V, \sigma(\alpha), \sigma(\beta),\left(\gamma_{i}\right)_{i \in I}\right)
$$

and then $\sigma \cdot S_{\mathcal{D}}=S_{\sigma \cdot \mathcal{D}} \in \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$.
In general, given a $k[\Sigma]$-algebra $A$ and an $A$-module $M$, there is a natural $\mathrm{T}^{0}(A)=A^{\sigma} /(N \cdot A)$-module structure on $\mathrm{T}^{*}(M)$. This equips $\mathrm{T}^{j}\left(\operatorname{Sht}_{(G, b, I), K} ; W\right)$ with a natural $\mathrm{T}^{0} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$-action. We are most interested in the special case where $W=\mathbb{1}$ and $b=1_{G}$. In this case we have $\mathrm{T}^{j}\left(\operatorname{Sht}_{(G, b, I), K} ; \mathbb{1}\right)=$ $\mathrm{T}^{j}\left(\mathrm{c}-\operatorname{Ind}_{K}^{G(E)} k\right)$ at the level of underlying $H(E)$-representations (cf. Example 8.5.1. . If an excursion datum $\mathcal{D}=\left(I, V, \alpha, \beta,\left(\gamma_{i}\right)_{i \in I}\right)$ is $\Sigma$-invariant, then $S_{\mathcal{D}} \in \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}$ and its action on $\mathrm{T}^{j}\left(\mathrm{c}-\operatorname{Ind}_{K}^{G(E)} k\right)$ can be described more concretely using 8.5): it is given by composition

8.5.3. Normed excursion action. Recall from Definition 7.1.1 that for any commutative $k[\Sigma]$-algebra $A$, there is the Tate diagonal morphism

$$
A \xrightarrow{\mathrm{Nm}} \mathrm{~T}^{0}(A)
$$

sending $a$ to the class of $\operatorname{Nm}(a)=a \cdot \sigma(a) \cdots \sigma^{\ell-1}(a)$. This is Frob-semilinear, but an $\mathbf{F}_{\ell}[\Sigma]$-structure on $A$ induces a linearization $\mathrm{Nm}^{\left(\ell^{-1}\right)}: A \rightarrow \mathrm{~T}^{0}(A)$ which is a $k$-algebra homomorphism.

We apply this to $A:=\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$, with the $\mathbf{F}_{\ell \text {-structure coming from the fact that } \widehat{G} \text { is defined over }}$ $\mathbf{F}_{\ell}$. In 8.5 .2 we saw an action of $\mathrm{T}^{0} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ on $\mathrm{T}^{j}\left(\mathrm{c}-\operatorname{Ind}_{K}^{G(E)} k\right)$. Inflating this action through $\mathrm{Nm}^{\left(\ell^{-1}\right)}$ gives an action of $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ on $\mathrm{T}^{j}\left(\mathrm{c}-\operatorname{Ind}_{K}^{G(E)} k\right)$, which we call the normed excursion action.
8.5.4. Native excursion action. The $\Sigma$-invariant subalgebra $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}$ acts naturally on $\mathrm{T}^{j}(\operatorname{Sht}(G, b, I), K ; V)$ via the quotient $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma} \rightarrow \mathrm{T}^{0}\left(\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)\right)$ and then the mechanism of 8.5.2. We refer to this as the native excursion action of $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}$ on $\mathrm{T}^{j}\left(\operatorname{Sht}_{(G, b, I), K} ; V\right)$. This action is not the same as the restriction of the normed excursion action to the subalgebra $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma} \subset \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$; this discrepancy will be responsible for Frobenius twists which show up later.

In general, for a commutative $k$-algebra $A$ the absolute Frobenius $A \rightarrow A$ is Frob-semilinear. If $A$ has an $\mathbf{F}_{\ell}$-structure $A \cong A_{0} \otimes_{\mathbf{F}_{\ell}} k$, then the absolute Frobenius may be linearized to a map $F: A \rightarrow A$, as explained in $\$ 7.1 .2$. The map $F$ is characterized as the unique $k$-linear homomorphism that sends $a_{0} \mapsto a_{0}^{\ell}$ for all $a_{0} \in A_{0} \subset A$.

The preceding discussion applies to $A:=\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}$ (with the $\mathbf{F}_{\ell}$-structure coming from the fact that $\widehat{G}$ is defined over $\left.\mathbf{F}_{\ell}\right)$. In these terms, the normed excursion action of $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}$ is the native excursion action composed with the map $F: \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma} \rightarrow \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}$ which is the linearization of the absolute Frobenius.
8.5.5. Norm of excursion data. For any finite group $Q$ over which the $W_{E}$-action on $\widehat{G}$ factors, we define a functor

$$
\operatorname{Nm}: \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right) \rightarrow \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right)^{B \Sigma}
$$

as follows:

- For a representation $V \in \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right)$, we set

$$
\operatorname{Nm}(V):=V \otimes_{k}\left({ }^{\sigma} V\right) \otimes_{k} \ldots \otimes_{k}\left(\sigma^{\ell-1} V\right) \in \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right)^{B \Sigma}
$$

with the obvious $\Sigma$-equivariant structure. Note that it corresponds under Geometric Satake to Definition 7.2.5,

- Given $h: V \rightarrow V^{\prime} \in \operatorname{Rep}_{k}\left(\left({ }^{L} G\right)^{I}\right)$, we set

$$
\operatorname{Nm}(h):=h \otimes{ }^{\sigma} h \otimes \ldots \otimes^{\sigma^{\ell-1}} h: \operatorname{Nm}(V) \rightarrow \operatorname{Nm}\left(V^{\prime}\right) .
$$

Note that Nm is not an additive functor, nor is it even $k$-linear.
Definition 8.5.2. We define the linearized norm $\mathrm{Nm}^{\left(\ell^{-1}\right)}:=\mathrm{Nm} \circ \mathrm{Frob}^{-1}$ to be the linearization of Nm in the sense of Construction 7.4.1; note that $\mathrm{Frob}^{-1}$ is the identity on objects and on morphisms it is $(-) \otimes_{k, \mathrm{Frob}^{-1}} k$. Then the resulting functor

$$
\operatorname{Nm}^{\left(\ell^{-1}\right)}: \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right) \rightarrow \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right)^{B \Sigma}
$$

is $k$-linear (although still not additive).
Definition 8.5.3. For $V \in \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right)$, we denote by

$$
N \cdot V \in \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right)^{B \Sigma}
$$

the $\sigma$-equivariant representation $V \oplus^{\sigma} V \oplus \ldots \oplus \sigma^{\ell-1} V$, with the obvious $\Sigma$-equivariant structure.
For $h: V \rightarrow V^{\prime} \in \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right)$, we denote by

$$
N \cdot h: N \cdot V \rightarrow N \cdot V^{\prime}
$$

the $\sigma$-equivariant map $h \oplus{ }^{\sigma} h \oplus \ldots \oplus^{\sigma^{\ell-1} h}$. Let $\Delta_{\ell}: \mathbb{1} \rightarrow \mathbb{1}^{\oplus \ell}$ denote the diagonal map and $\nabla_{\ell}: \mathbb{1}^{\oplus \ell} \rightarrow \mathbb{1}$ denote the sum map.

Definition 8.5.4. Let $\mathcal{D}=\left(I, V, \alpha, \beta,\left(\gamma_{i}\right)_{i \in I}\right)$ be an excursion datum for $\widehat{G}$. Define the excursion data

$$
\operatorname{Nm}^{\left(\ell^{-1}\right)} \mathcal{D}:=\left(I, \operatorname{Nm}^{\left(\ell^{-1}\right)} V, \operatorname{Nm}^{\left(\ell^{-1}\right)} \alpha, \operatorname{Nm}^{\left(\ell^{-1}\right)} \beta,\left(\gamma_{i}\right)_{i \in I}\right)
$$

and

$$
N \cdot \mathcal{D}:=\left(I, N \cdot V,(N \cdot \alpha) \circ \Delta_{\ell}, \nabla_{\ell} \circ(N \cdot \beta),\left(\gamma_{i}\right)_{i \in I}\right)
$$

which are excursion data for $\widehat{G}$.
Straightforward calculations yield:
Lemma 8.5.5 ([|Fen, Lemma 5.16]). For all excursion data $\mathcal{D}$, we have

$$
\operatorname{Nm}^{\left(\ell^{-1}\right)}\left(S_{\mathcal{D}}\right)=S_{\mathrm{Nm}^{\left(\ell^{-1}\right)}(\mathcal{D})} \in \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}
$$

and

$$
N \cdot S_{\mathcal{D}}=S_{N \cdot \mathcal{D}} \in \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}
$$

Proof. The second identity appears in [Fen, Lemma 5.16], which also proves that

$$
\operatorname{Nm}\left(S_{\mathcal{D}}\right)=S_{\operatorname{Nm}(\mathcal{D})} \in \operatorname{Exc}_{k}(\Gamma, \widehat{G})^{\sigma}
$$

from which the first identity follows.
8.6. Functoriality for excursion operators. For basic $b \in B(H)$, we let $H_{b}$ be the corresponding inner twist of $H$, as in $\$ 4.4$. If $b \in B(H)$ is basic and maps to $1_{G} \in B(G)$, then we have $\iota_{b^{\prime}}: H_{b^{\prime}} \hookrightarrow G_{\iota\left(b^{\prime}\right)}=G$. Below we abbreviate $\iota^{*} K:=\iota_{b^{\prime}}^{*} K$ and 1 for the trivial element of $B(G)$ or $B\left(H_{b^{\prime}}\right)$, depending on context.

Proposition 8.6.1. Assume $\ell>\max \{b(\widehat{G}), b(\widehat{H})\}$. Let $K<G(E)$ be a pro-p compact open subgroup stable under $\Sigma$. Then for any $\varepsilon \in \mathbf{Z} / 2 \mathbf{Z}$ and each non-empty finite set $I$, there is a natural isomorphism

$$
\begin{equation*}
\mathrm{T}^{\varepsilon}\left(\operatorname{Sht}_{(G, 1, I), K} ; \operatorname{Nm}^{\left(\ell^{-1}\right)}(V)\right) \cong \bigoplus_{b^{\prime} \in \iota^{-1}\left(1_{G}\right)} \mathrm{T}^{\varepsilon}\left(\operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota^{*} K}^{b^{\prime}} ;{ }^{L} \psi^{*}(V)\right) \tag{8.9}
\end{equation*}
$$

of functors

$$
\operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right) \rightarrow D\left(\operatorname{Rep}_{k}^{\mathrm{sm}} H(E)\right)^{B} \prod_{i \in I} W_{E}
$$

Moreover, these natural isomorphisms are compatible with fusion along all maps of non-empty finite sets $\zeta: I \rightarrow J$.

The meaning of the last sentence is as follows. As explained in 8.1.3, any such $\zeta: I \rightarrow J$ induces a restriction functor $\operatorname{Res}_{\zeta}: \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{I}\right) \rightarrow \operatorname{Rep}_{k}\left((\widehat{G} \rtimes Q)^{J}\right)$. The natural isomorphism 8.2 induces a natural isomorphism

$$
\begin{equation*}
\mathrm{T}^{\varepsilon}\left(\operatorname{Sht}_{(G, 1, I), K} ; W\right) \cong \mathrm{T}^{\varepsilon}\left(\operatorname{Sht}_{(G, 1, J), K} ; \operatorname{Res}_{\zeta} W\right) \tag{8.10}
\end{equation*}
$$

compatible with compositions of maps of finite sets, and similarly for each $b^{\prime} \in \iota^{-1}\left(1_{G}\right)$ a natural isomorphism

$$
\begin{equation*}
\mathrm{T}^{\varepsilon}\left(\operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota^{*} K}^{b^{\prime}} ;{ }^{L} \psi^{*}(W)\right) \cong \mathrm{T}^{\varepsilon}\left(\operatorname{Sht}_{\left(H, 1_{H}, J\right), \iota^{*} K}^{b^{\prime}} ;{ }^{L} \psi^{*}\left(\operatorname{Res}_{\zeta} W\right)\right) \tag{8.11}
\end{equation*}
$$

compatible with compositions of maps of finite sets. Then "compatible with fusion" means that for every $\zeta: I \rightarrow J$, the diagram below commutes:

$$
\begin{aligned}
& \mathrm{T}^{\varepsilon}\left(\operatorname{Sht}_{(G, 1, I), K} ; \operatorname{Nm}^{\left(\ell^{-1}\right)}(V)\right) \underset{\sqrt{8.9}}{\sim} \bigoplus_{b^{\prime} \in \iota^{-1}\left(1_{G}\right)} \mathrm{T}^{\varepsilon}\left(\operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota^{*} K}^{b^{\prime}} ;{ }^{L} \psi^{*}(V)\right) \\
& 8.10 \downarrow \sim \quad \text { 8.11] } \downarrow \sim \\
& \mathrm{T}^{\varepsilon}\left(\operatorname{Sht}_{(G, 1, J), K} ; \operatorname{Nm}^{\left(\ell^{-1}\right)}\left(\operatorname{Res}_{\zeta} V\right)\right) \underset{\boxed{8.9}}{\stackrel{\sim}{4}} \bigoplus_{b^{\prime} \in \iota^{-1}\left(1_{G}\right)} \mathrm{T}^{\varepsilon}\left(\operatorname{Sht}_{\left(H, 1_{H}, J\right), \iota^{*} K}^{b^{\prime}} ;{ }^{L} \psi^{*}\left(\operatorname{Res}_{\zeta} V\right)\right)
\end{aligned}
$$

Proof. For each $b^{\prime} \in \iota^{-1}\left(1_{G}\right) \subset B(H)$, the commutative diagram

induces a natural isomorphism $\iota^{*}\left(\pi_{K}^{G}\right)^{*} \cong\left(\pi_{\iota^{*} K}^{H}\right)^{*} \iota^{*}$, hence natural isomorphisms

$$
\begin{equation*}
\mathbb{T}^{*} \iota^{*}\left(\pi_{K}^{G}\right)^{*}\left(\mathcal{S}_{\mathrm{Nm}^{\left(\ell^{-1}\right)}(V)}\right) \cong \mathbb{T}^{*}\left(\pi_{\iota^{*} K}^{H}\right)^{*} \iota^{*}\left(\mathcal{S}_{\mathrm{Nm}^{\left(\ell^{-1}\right)}(V)}\right) \cong\left(\pi_{\iota^{*} K}^{H}\right)^{*} \mathbb{T}^{*} \iota^{*}\left(\mathcal{S}_{\mathrm{Nm}^{(\ell-1)}(V)}\right) \in \operatorname{Shv}\left(\operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota^{*} K}^{b^{\prime}} ; \mathcal{T}_{k}\right) \tag{8.12}
\end{equation*}
$$

compatible with fusion. Theorem 7.7.1 supplies natural isomorphisms

$$
\begin{equation*}
\left(\pi_{\iota^{*} K}^{H}\right)^{*} \mathbb{T}^{*} \iota^{*}\left(\mathcal{S}_{\mathrm{Nm}^{\left(\ell^{-1}\right)}(V)}\right) \cong\left(\pi_{\iota^{*} K}^{H}\right)^{*} \mathbb{T}^{*}\left(\mathcal{S}_{L} \psi^{*}(V), \operatorname{Shv}\left(\operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota^{*} K}^{b^{\prime}} ; \mathcal{T}_{k}\right),\right. \tag{8.13}
\end{equation*}
$$

compatible with fusion.
We now consider Tate cohomology of the moduli of shtukas. To distinguish between $G$ and $H$, we write

$$
\begin{gathered}
f_{K}^{G}: \operatorname{Sht}_{(G, 1, I), K} \rightarrow \prod_{i \in I} \operatorname{Spd} \breve{E} \\
f_{K}^{H, b^{\prime}}: \operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota^{*} K}^{b^{\prime}} \rightarrow \prod_{i \in I} \operatorname{Spd} \breve{E} .
\end{gathered}
$$

Note that support of any Satake sheaf on $\operatorname{Sht}_{(G, 1, I), K}$ has finite dim. $\operatorname{trg}$ over $\prod \operatorname{Spd} \breve{E}$ and is extra small (cf. Example 3.1.4, and similarly for $\operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota^{*} K}^{b^{\prime}}$. $\operatorname{As} \operatorname{Fix}\left(\sigma, \operatorname{Sht}_{(G, b, I), K}\right)$ is a finite union of spaces of the form $\operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota^{*} K}^{b^{\prime}}$ by Proposition 4.4.7. the results of $\$ 3$ apply. In particular, we may apply Proposition 3.6.2 which relates the Tate cohomology of $\operatorname{Sht}_{(G, 1, I), K}$ to that of its fixed points, and Proposition 4.4.7, which identifies these fixed points; combining these with 8.12 and 8.13) gives a sequence of natural isomorphisms

$$
\left.\begin{array}{rl} 
& \mathbb{T}^{*} \mathrm{R}\left(f_{K}^{G}\right)!\left(\left(\pi_{K}^{G}\right)^{*} \mathcal{S}_{\mathrm{Nm}^{\left(\ell^{-1}\right)}(V)}\right) \\
\text { Propositions } 3.6 .2 \& 4.4 .7 & \Longrightarrow \bigoplus_{b^{\prime} \in \iota^{-1}\left(1_{G}\right)} \mathrm{R}\left(f_{K}^{H, b^{\prime}}\right)!\mathbb{T}^{*} \iota^{*}\left(\left(\pi_{K}^{G}\right)^{*} \mathcal{S}_{\mathrm{Nm}}{ }^{(\ell-1)}(V)\right.
\end{array}\right)
$$

compatible with fusion. The result then follows upon applying the Tate cohomology functor $\mathrm{T}^{\varepsilon}(-)$.

In particular, when $V=\mathbb{1}$ is the trivial representation we have an identification

$$
\begin{equation*}
\mathrm{T}^{0}\left(\operatorname{Sht}_{(G, 1,\{0\}), K} ; \mathbb{1}\right) \cong \bigoplus_{b^{\prime} \in \iota^{-1}\left(1_{G}\right)} \mathrm{T}^{0}\left(\operatorname{Sht}_{\left(H, 1_{H},\{0\}\right), \iota^{*} K}^{b^{\prime}} ; \mathbb{1}\right) \tag{8.14}
\end{equation*}
$$

Note that the $H_{b^{\prime}}$ for $b^{\prime} \in \iota^{-1}\left(1_{G}\right)$ are inner twists of each other, so their $L$-groups ${ }^{L} H_{b^{\prime}}$ are all canonically identified, hence we may identify each of their excursion algebras with $\operatorname{Exc}_{k}\left(W_{E}, \widehat{H}\right)$.

Theorem 8.6.2. Assume $\ell>\max \{b(\widehat{G}), b(\widehat{H})\}$. Let $K<G(E)$ be a pro-p compact open subgroup stable under $\Sigma$. Then the isomorphism (8.14) is equivariant for the action of $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$, acting on the LHS via the normed excursion action (\$8.5.3) and on the RHS through the homomorphism ${ }^{L} \psi^{*}: \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right) \rightarrow$ $\operatorname{Exc}_{k}\left(W_{E}, \widehat{H}\right)$ from 8.3) followed by the native excursion action (8.5.4).

Proof. Let $\mathcal{D}=\left(I, V, \alpha, \beta,\left(\gamma_{i}\right)_{i \in I}\right)$ be an excursion datum for $\widehat{G}$. By the definition of the excursion action (cf. 8.5), what we have to show is that the action of $\mathrm{Nm}^{\left(\ell^{-1}\right)} S_{\mathcal{D}} \in \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}$ on $\mathrm{T}^{0}(\operatorname{Sht}(G, 1,\{0\}), K ; \mathbb{1})$ is intertwined with the action of $S_{L} \psi^{*}(\mathcal{D}) \in \operatorname{Exc}\left(W_{E},{ }^{L} H\right)$ on $\bigoplus_{b^{\prime} \in \iota^{-1}\left(1_{G}\right)} \mathrm{T}^{0}\left(\operatorname{Sht}_{\left(H, 1_{H},\{0\}\right), \iota^{*} K}^{b^{\prime}} ; \mathbb{1}\right)$ under the identification 8.14).

By Lemma 8.5.5 we have $\mathrm{Nm}^{\left(\ell^{-1}\right)} S_{\mathcal{D}}=S_{\mathrm{Nm}^{\left(\ell^{-1}\right)} \mathcal{D}}$, whose excursion action is calculated by the left column in the diagram below:

$$
\begin{align*}
& \begin{array}{c}
\mathrm{T}^{0}\left(\operatorname{Sht}_{(G, 1, I), K} ; \mathbb{1}\right) \longleftrightarrow \sim \bigoplus_{b^{\prime} \in \iota^{-1}\left(1_{G}\right)} \mathrm{T}^{0}\left(\operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota^{*} K}^{b^{\prime}} ; \mathbb{1}\right) \\
\downarrow \mathrm{Nm}^{\left(\ell^{-1}\right)}(\alpha)
\end{array} \\
& \begin{array}{c}
\mathrm{T}^{0}\left(\operatorname{Sht}_{(G, 1, I), K} ; \operatorname{Nm}^{\left(\ell^{-1}\right)}(V)\right) \stackrel{\sim}{\longleftrightarrow} \bigoplus_{b^{\prime} \in \iota^{-1}\left(1_{G}\right)} \mathrm{T}^{0}\left(\operatorname{Sht}_{\left(H, 1_{H}, I\right), \iota^{*} K}^{b^{\prime}} ;{ }^{L} \psi^{*}(V)\right) \\
\downarrow^{\left(\gamma_{i}\right)_{i \in I}}
\end{array} \tag{8.15}
\end{align*}
$$

Meanwhile, $S_{L^{*}(\mathcal{D})}$ is calculated by the right column in the diagram. Proposition 8.6.1 establishes the horizontal identifications making all diagrams commutes, which gives the result.

## 9. Derived Treumann-Venkatesh Conjecture

In this section we will reap the applications of the preceding material, especially the functoriality relations for excursion operators from Theorem 8.6.2. In 89.1 we formulate the "derived" version of TreumannVenkatesh's Conjecture 1.2 .3 (2), and prove it in 9.4 In 9.2 we will construct the Treumann-Venkatesh homomorphism alluded to in $(1.6$, and in $\$ 9.3$ we establish the commutative square (1.7). Finally, in $\S 9.5$ we prove the existence of functorial lifts along $\sigma$-dual homomorphisms, including Theorem 1.4.1.
9.1. Formulation. By the realization of the Bernstein center $\mathfrak{Z}(G)$ as the ring of endomorphisms of the identity functor on $D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G(E)\right)$, there is a tautological action of $\mathfrak{Z}(G)$ on any $\Pi \in D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G(E)\right)$. Composing this with the Fargues-Scholze map $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right) \xrightarrow{\mathrm{FS}_{G}} \mathfrak{Z}(G ; k)$ discussed in 8.4 we obtain an action of $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ on any such $\Pi$. In particular, to each $\Pi$ we may attach a subset

$$
\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)}\left(\mathrm{H}^{*}(\Pi)\right) \subset \operatorname{Spec} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)
$$

which can be interpreted as the "set of semi-simple $L$-parameters attached to $\Pi$ ". For example, if $\Pi \in$ $\operatorname{Rep}_{k}^{\mathrm{sm}} G(E)$ is irreducible admissible then $\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)}(\Pi)$ is necessarily a single closed point, corresponding to the Fargues-Scholze parameter $\rho_{\Pi} \in H^{1}\left(W_{E} ; \widehat{G}(k)\right)$. This defines the map 1.2).

Let $\Pi \in D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}}(G(E) \rtimes \Sigma)\right)=D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G(E)\right)^{B \Sigma}$. Then we may form the Tate cohomology $\mathrm{T}^{j}(\Pi)$, which is naturally an object of $\operatorname{Rep}_{k}^{\mathrm{sm}} H(E)$.

Let $F: \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right) \rightarrow \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ be the linearized Frobenius (cf. 88.5.4), which is a $k$-algebra homomorphism. This induces a functor $F_{*}$ on $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$-modules.

Theorem 9.1.1. Assume $\ell>\max \{b(\widehat{G}), b(\widehat{H})\}$. Then for any $j \in \mathbf{Z} / 2 \mathbf{Z}$, $\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{H}\right)}\left(\mathrm{T}^{j}(\Pi)\right)$ lies over $F_{*} \operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)}\left(\mathrm{H}^{*}(\Pi)\right)$ with respect to the map $\operatorname{Spec}^{\operatorname{Exc}}{ }_{k}\left(W_{E}, \widehat{H}\right) \xrightarrow{{ }^{L} \psi_{*}} \operatorname{Spec} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ induced by the $\sigma$-dual homomorphism ${ }^{L} \psi:{ }^{L} H \rightarrow{ }^{L} G$. In other words, there is a commutative diagram

Example 9.1.2 (Treumann-Venkatesh functoriality conjecture). If $\Pi$ is an irreducible smooth representation of $G(E)$, then $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ acts on $\Pi$ through a character $\chi_{\Pi}$. The composition $\chi_{\Pi} \circ F$ is the character of
$\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ associated to the Frobenius twist $\Pi^{(\ell)}:=\Pi \otimes_{k, \mathrm{Frob}_{\ell}} k$, so we have

$$
F_{*} \operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)}(\Pi)=\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)}\left(F_{*} \Pi\right)=\left\{\chi_{\Pi(\ell)}\right\} .
$$

Suppose furthermore that $\Pi \cong{ }^{\sigma} \Pi \in \operatorname{Rep}_{k}^{\mathrm{sm}} G(E)$. Then by TV16, Proposition 6.1], the $G(E)$-action on $\Pi$ extends uniquely to a $G(E) \rtimes \Sigma$-action. Then Theorem 9.1.1 implies, assuming $\ell>\max \{b(\widehat{G}), b(\widehat{H})\}$, that for each $j \in \mathbf{Z} / 2 \mathbf{Z}$ and each irreducible $H(E)$-subquotient $\pi$ of $\mathrm{T}^{i}(\Pi)$, the semi-simple $L$-parameter $\rho_{\Pi^{(\ell)}} \in \mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)$ is the image of the semi-simple $L$-parameter $\rho_{\pi}$ under the map $\mathrm{H}^{1}\left(W_{E} ; \widehat{H}(k)\right) \xrightarrow{{ }^{L} \psi_{*}}$ $\mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)$. This implies Theorem 1.3.1.

Example 9.1.3. Suppose $\sigma$ is an inner automorphism, induced by conjugation by $s \in G(E)$ (which therefore has to be an $\ell$-torsion element). Then we have an isomorphism $G(E) \rtimes \Sigma \xrightarrow{\sim} G(E) \times \Sigma$ sending $(g, \sigma) \mapsto$ $\left(g s^{-1}, \sigma\right)$. Hence we get a functor

$$
D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G(E)\right) \rightarrow D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}}(G(E) \times \Sigma)\right) \xrightarrow{\sim} D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}}(G(E) \rtimes \Sigma)\right) .
$$

This equips every representation $\Pi \in D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G(E)\right)$ with a canonical $\Sigma$-equivariant structure, where $\sigma$ acts by $\Pi(s)$.
9.2. The Treumann-Venkatesh homomorphism. We next establish some technical lemmas which aid to study the properties of the Brauer homomorphism.

Proposition 9.2.1. Let $K \subset G$ be a $\Sigma$-stable pro-p compact open subgroup. Then the natural map

$$
\iota^{*} K \backslash H(E) / \iota^{*} K \rightarrow K \backslash G(E) / K
$$

is injective.
Proof. Let $a, b \in \iota^{*} K \backslash H(E)$ be two elements whose images in $K \backslash G(E)$ lie in the same orbit for the right translation of $K$. In other words, $a=b \kappa$ for some $\kappa \in K$. Applying $\sigma$ to this equation, and using that $a, b$ are fixed by $\sigma$, we obtain $a=b \sigma(\kappa)$, so $\sigma(\kappa) \kappa^{-1} \in \operatorname{Stab}_{K}(b)$. Since $\Sigma$ is of order $\ell$ while $K$ is pro- $p$, we have $\mathrm{H}^{1}\left(\Sigma ; \operatorname{Stab}_{K}(b)\right)=0$. Hence there exists $y \in \operatorname{Stab}_{K}(b)$ such that $\sigma(\kappa) \kappa^{-1}=\sigma(y) y^{-1}$. Then $y^{-1} \kappa$ is fixed by $\sigma$, so $y^{-1} \kappa \in H(E) \cap K=\iota^{*} K$. But then

$$
a=b \kappa=\left(b y^{-1}\right) \kappa=b\left(y^{-1} \kappa\right)
$$

which shows that $a$ and $b$ lie in the same orbit for the right translation of $\iota^{*} K$ on $\iota^{*} K \backslash H(E)$.
Recall that we defined a compact open subgroup $K \subset G(E)$ to be plain if the natural map $H(E) / \iota^{*} K \rightarrow$ $[G(E) / K]^{\sigma}$ is an isomorphism. By a similar argument involving the vanishing of non-abelian cohomology (cf. [Fen, Lemma 6.6]), any pro- $p$ subgroup $K \subset G(E)$ is plain, so the (un-normalized) Brauer homomorphism (cf. ©7.1.1) $\mathrm{Br}: \mathscr{H}(G, K)^{\sigma} \rightarrow \mathscr{H}\left(H, \iota^{*} K\right)$ is defined for any such $K$.

Corollary 9.2.2. Let $K \subset G$ be a $\Sigma$-stable pro-p compact open subgroup. Then Br induces a map of centers,

$$
\begin{equation*}
\operatorname{Br}: Z\left(\mathscr{H}(G, K)^{\sigma}\right) \rightarrow Z\left(\mathscr{H}\left(H, \iota^{*} K\right)\right) \tag{9.1}
\end{equation*}
$$

Proof. Proposition 9.2.1 implies that $\mathrm{Br}: \mathscr{H}(G, K)^{\sigma} \rightarrow \mathscr{H}\left(H, \iota^{*} K\right)$ is a surjective $k$-algebra homomorphism, so it maps the center to the center.

It is evident from the definition that the map 9.1 factors over the quotient $Z\left(\mathscr{H}(G, K)^{\sigma}\right) / N \cdot \mathfrak{Z}(G, K)$, which induces a map

$$
\begin{equation*}
\mathrm{T}^{0} \mathfrak{Z}(G, K)=\frac{\mathfrak{Z}(G, K)^{\sigma}}{N \cdot \mathfrak{Z}(G, K)} \hookrightarrow \frac{Z\left(\mathscr{H}(G, K)^{\sigma}\right)}{N \cdot \mathfrak{Z}(G, K)} \rightarrow \mathfrak{Z}\left(H, \iota^{*} K\right) \tag{9.2}
\end{equation*}
$$

Note that we have a natural $\mathbf{F}_{\ell \text {-structure on }} \mathfrak{Z}(G, K ; k)$ given by

$$
\begin{equation*}
\mathfrak{Z}(G, K ; k)=\mathfrak{Z}\left(G, K ; \mathbf{F}_{\ell}\right) \otimes_{\mathbf{F}_{\ell}} k \tag{9.3}
\end{equation*}
$$

The following is a "normalized" (cf. 7.1.3) version of 9.1), in the sense of the normalized Brauer homomorphism 7.4.

Definition 9.2.3. Let $K \subset G$ be a $\Sigma$-stable pro-p compact open subgroup. We define Treumann-Venkatesh homomorphism

$$
\mathfrak{Z}_{\mathrm{TV}, K}: \mathfrak{Z}(G, K) \rightarrow \mathfrak{Z}\left(H, \iota^{*} K\right)
$$

to be the composition of (9.2) with the map $\mathrm{Nm}^{\left(\ell^{-1}\right)}: \mathfrak{Z}(G, K) \rightarrow \mathrm{T}^{0}(\mathfrak{Z}(G, K))$ from Definition 7.1.1, with respect to the $\mathbf{F}_{\ell}$-structure 9.3 ).
9.3. Modular functoriality for Bernstein centers. For an inclusion $K \subset K^{\prime} \subset G(E)$ of $\Sigma$-stable pro- $p$ compact open subgroups, we have the map $e_{G}^{K} \rightarrow K^{\prime}: \mathfrak{Z}(G, K) \rightarrow \mathfrak{Z}\left(G, K^{\prime}\right)$ given by convolution with $\mathbb{1}_{K^{\prime}}$. Similarly, we have $e_{H}^{K \rightarrow K^{\prime}}: \mathfrak{Z}\left(H, \iota^{*} K\right) \rightarrow \mathfrak{Z}\left(H, \iota^{*} K\right)$ given by convolution with $\mathbb{1}_{\iota^{*} K^{\prime}}$. The diagram

$$
\begin{aligned}
& \mathfrak{Z}(G, K) \xrightarrow{\mathfrak{Z} \mathrm{vv}, K} \mathfrak{Z}\left(H, \iota^{*} K\right) \\
& \qquad e_{G}^{K \rightarrow K^{\prime}} \downarrow_{H}^{K \rightarrow K^{\prime}} \\
& \mathfrak{Z}\left(G, K^{\prime}\right) \xrightarrow{\boldsymbol{Z}_{\mathrm{Tv}, K^{\prime}}} \mathfrak{Z}\left(H, \iota^{*} K^{\prime}\right)
\end{aligned}
$$

commutes.
Definition 9.3.1 (Base change homomorphism for Bernstein centers). We define the Treumann-Venkatesh homomorphism (for Bernstein centers) $\mathfrak{Z}_{\mathrm{TV}}: \mathfrak{Z}(G) \rightarrow \mathfrak{Z}(H)$ as
where the limit is taken over $\Sigma$-stable pro-p compact open subgroups $K \subset G(E)$.
Assume $\ell>\max \{b(\widehat{G}), b(\widehat{H})\}$. Recall that in Corollary 7.6 .2 we have constructed the $\sigma$-dual homomorphism ${ }^{L} \psi:{ }^{L} H \rightarrow{ }^{L} G$ over $k$.

Theorem 9.3.2. Assume $\ell>\max \{b(\widehat{G}), b(\widehat{H})\}$. Then the following diagram commutes:

Note that if $K$ is a plain subgroup of $G(E)$, then we have

$$
\begin{equation*}
\mathrm{T}^{0}\left({\mathrm{c}-\operatorname{Ind}_{K}^{G(E)}}^{G}\right) \cong{\mathrm{c}-\operatorname{Ind}_{\iota^{*} K}^{H(E)}}_{H \in \operatorname{Rep}_{k}^{\mathrm{sm}} H(E) . . . . .} \tag{9.5}
\end{equation*}
$$

(This is a special case of $\left[\mathrm{BFH}^{+}\right.$, Proposition 8.12]; more general results on the interaction of Tate cohomology with compact induction are discussed later in $\$ 10.4$.)

In preparation for the proof of Theorem 9.3 .2 , we record the following interpretation of the Brauer homomorphism.
Lemma 9.3.3. Under the identifications $\mathscr{H}(G, K) \cong \operatorname{End}_{G(E)}\left(\mathrm{c}-\operatorname{Ind}_{K}^{G(E)} k\right)$ and $\mathscr{H}\left(H, \iota^{*} K\right) \cong \operatorname{End}_{H(E)}\left({\mathrm{c}-\operatorname{Ind}_{\iota^{*} K}^{H(E)}}^{H( }\right)$, the map $\mathrm{Br}: \mathrm{T}^{0} \mathscr{H}(G, K) \rightarrow \mathscr{H}\left(H, \iota^{*} K\right)$ induced by the Brauer homomorphism is identified with the map

$$
\mathrm{T}^{0} \operatorname{End}_{G(E)}\left({\mathrm{c}-\operatorname{Ind}_{K}^{G(E)}}^{G(E)} \rightarrow \operatorname{End}_{H(E)}\left(\mathrm{T}^{0}\left(\mathrm{c}-\operatorname{Ind}_{K}^{G(E)} k\right)\right) \stackrel{9.5}{=} \operatorname{End}_{H(E)}\left(\mathrm{c}-\operatorname{Ind}_{\iota^{*} K}^{H(E)} k\right)\right.
$$

sending a $\Sigma$-equivariant endomorphism of $\mathrm{c}-\operatorname{Ind}_{K}^{G(E)} k$ to the induced endomorphism on its Tate cohomology.
Proof. Apply [Fen, Lemma 6.7] (which comes from TV16, §6.2]) with $\Pi:={\operatorname{c}-\operatorname{Ind}_{K}^{G(E)}}^{G(E}$.
Proof of Theorem 9.3.2. For any pro- $p$, $\Sigma$-stable compact open subgroup $K \subset G(E)$, we also denote by

$$
\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right) \xrightarrow{\mathrm{FS}_{G}} \mathfrak{Z}(G, K)
$$

the composition of $\mathrm{FS}_{G}$ with the projection $\mathfrak{Z}(G) \rightarrow \mathfrak{Z}(G, K)$. Applying Tate cohomology, this induces

$$
\begin{equation*}
\mathrm{T}^{0} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right) \xrightarrow{\mathrm{FS}_{G}} \mathrm{~T}^{0} \mathfrak{Z}(G, K) \tag{9.6}
\end{equation*}
$$

We have identifications

$$
\begin{aligned}
& \text { Ex. } 8.5 .1] \sim
\end{aligned}
$$

and for any excursion datum $\mathcal{D}$ for $\widehat{G}$, Theorem 8.6.2 implies that these identifications intertwine

$$
\begin{equation*}
\binom{\text { the action of } S_{\mathrm{Nm}^{\left(\ell^{-1}\right)}} \mathcal{D}}{\text { on }^{0}\left(\mathrm{c}-\operatorname{Ind}_{K}^{G(E)} k\right)}=\binom{\text { the action of } S_{L} \psi^{*} \mathcal{D}}{\operatorname{on~c-Ind}_{\iota^{*} K}^{H(E)} k} \text {. } \tag{9.7}
\end{equation*}
$$

The diagram

commutes by the definition of Nm , and the fact that $\mathrm{FS}_{G}$ is defined over $\mathbf{F}_{\ell}$ (with respect to the $\mathbf{F}_{\ell \text {-structures }}$ used to linearize Nm on each row). Therefore, unraveling the definition of $\mathfrak{Z}_{\mathrm{TV}}$ and using Lemma 8.5.5, it suffices to show that

$$
\begin{equation*}
\operatorname{Br}\left(\operatorname{FS}_{G}\left(S_{\mathrm{Nm}^{(\ell-1)} \mathcal{D}}\right)\right)=\operatorname{FS}_{H}\left(S_{L} \psi^{*} \mathcal{D}\right) \tag{9.9}
\end{equation*}
$$

for all excursion data $\mathcal{D}$ for $\widehat{G}$. By Lemma 9.3.3. $\operatorname{Br}\left(\mathrm{FS}_{G}\left(S_{\mathrm{Nm}^{\left(\ell^{-1}\right)} \mathcal{D}}\right)\right)$ is the endomorphism of $\mathrm{T}^{0}\left(\mathrm{c}-\operatorname{Ind}_{\iota^{*} K}^{H(E)} k\right)=$ c- $\operatorname{Ind}_{\iota^{*} K}^{H(E)} k$ obtained by taking $\mathrm{T}^{0}$ of the action of $S_{\mathrm{Nm}^{\left(e^{-1}\right)} \mathcal{D}}$ on c- $\operatorname{Ind}_{K}^{G(E)} k$, which according to 9.7 is the endomorphism given by $\mathrm{FS}_{H}\left(S_{L^{*} \mathcal{D}}\right)$.

Corollary 9.3.4. Assume $\ell>\max \{b(\widehat{G}), b(\widehat{H})\}$. Then for any irreducible $H(E)$-representation $\pi$, the character

$$
\chi_{\pi} \circ \mathfrak{Z}_{\mathrm{TV}}: \mathfrak{Z}(G) \xrightarrow{\mathfrak{Z}_{\mathrm{TV}}} \mathfrak{Z}(H) \xrightarrow{\chi_{\pi}} k
$$

has the property that for any irreducible $G(E)$-representation $\Pi$ on which $\mathfrak{J}(G)$ acts through $\chi_{\pi} \circ \mathfrak{Z}_{\mathrm{TV}}$, there is an isomorphism of semi-simple L-parameters $\rho_{\Pi} \cong{ }^{L} \psi \circ \rho_{\pi}$.
9.4. Proof of Theorem 9.1.1. It was seen in the proof of Theorem 9.3.2 that for any $\sum$-stable open compact subgroup $K<G(E)$, the normed action (cf. 8.5.3 of $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ on $\mathrm{T}^{j}\left(\operatorname{cc}^{-\operatorname{Ind}_{K}^{G(E)}} k\right)$ coincides under the identification (9.5) with the action obtained by composing $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right) \xrightarrow{\mathrm{FS}_{G}} \mathfrak{Z}(G) \xrightarrow{\mathcal{Z}_{\mathrm{Tv}}} \mathfrak{Z}(H)$ with the tautological action of $\mathfrak{Z}(H)$ on $\mathrm{c}-\operatorname{Ind}_{\iota^{*} K}^{H(E)} k$. Therefore, by Theorem 9.3.2, for any $j$ the map ${ }^{L} \psi_{*}: \operatorname{Spec} \operatorname{Exc}_{k}\left(W_{E}, \widehat{H}\right) \rightarrow \operatorname{Spec} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ carries

$$
\begin{equation*}
\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{H}\right)}^{\text {native }} \mathrm{T}^{j}(\Pi) \xrightarrow{{ }^{L} \psi_{*}} \operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)}^{\text {normed }} \mathrm{T}^{j}(\Pi), \tag{9.10}
\end{equation*}
$$

where the native excursion action is defined in 88.5.4.
We will compare the support of the normed and native actions of $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}$ on $\mathrm{T}^{j}(\Pi)$. By the discussion in 8.5 .3 we have for any $j \in \mathbf{Z} / 2 \mathbf{Z}$ an equality

$$
\begin{equation*}
\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}}^{\text {normed }}\left(\mathrm{T}^{j}(\Pi)\right)=F_{*} \operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}}^{\text {native }}\left(\mathrm{T}^{j}(\Pi)\right) \subset \operatorname{Spec} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma} \tag{9.11}
\end{equation*}
$$

By the Tate spectral sequence $\mathrm{T}^{j}\left(\mathrm{H}^{i}(\Pi)\right) \Longrightarrow \mathrm{T}^{i+j}(\Pi)$, each $\mathrm{T}^{n}(\Pi)$ has a finite filtration each of whose graded pieces is a subquotient of $\mathrm{H}^{*}(\Pi)$, hence we have

$$
\begin{equation*}
F_{*} \operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}}^{\text {native }}\left(\mathrm{T}^{j}(\Pi)\right) \subset F_{*} \operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}}^{\text {native }}\left(\mathrm{H}^{*}(\Pi)\right)=\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}}^{\text {native }}\left(F_{*} \mathrm{H}^{*}(\Pi)\right) \tag{9.12}
\end{equation*}
$$

Let $q$ : Spec $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right) \rightarrow$ Spec $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}$ be the map of spectra induced by the obvious inclusion. Combining 9.11 and 9.12 with 9.10 yields

$$
\begin{equation*}
q \circ{ }^{L} \psi_{*}\left(\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{H}\right)}^{\text {native }} \mathrm{T}^{j}(\Pi)\right) \subset F_{*} \operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}}^{\text {native }}\left(\mathrm{H}^{*}(\Pi)\right) \tag{9.13}
\end{equation*}
$$

The surjection $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma} \rightarrow \mathrm{T}^{0} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ induces a closed embedding on spectra, as in the diagram

$$
\operatorname{Spec} \mathrm{T}^{0} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right) \longleftrightarrow \operatorname{Spec} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}
$$

Now, [Fen, Lemma 5.15] says that any character from $\mathrm{T}^{0} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ to any perfect field has a unique extension to $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$, which implies that the map $\operatorname{Spec} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right) \rightarrow \operatorname{Spec} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}$ is one-toone (and surjective) over the closed subscheme $\operatorname{Spec} \mathrm{T}^{0} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right) \subset \operatorname{Spec} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)^{\sigma}$. From Theorem 8.6.2, we see that $q \circ{ }^{L} \psi_{*}\left(\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{H}\right)}^{\text {nativ }} \mathrm{T}^{j}(\Pi)\right)$ lands inside this subspace, so we may lift 9.13 to the containment

$$
\begin{equation*}
{ }^{L} \psi_{*}\left(\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{H}\right)}^{\text {native }} \mathrm{T}^{j}(\Pi)\right) \subset F_{*} \operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)}^{\text {native }}(\Pi) \tag{9.14}
\end{equation*}
$$

as desired.
9.5. Existence of functorial lifts. We generalize the proof of [Fen, Theorem 6.26] to prove the existence of functorial liftings along any $\sigma$-dual homomorphism.
Theorem 9.5.1. Assume $\ell>\max \{b(\widehat{G}), b(\widehat{H})\}$. Let $\pi$ be an irreducible representation of $H(E)$ over $k$, with Fargues-Scholze parameter $\rho_{\pi} \in \mathrm{H}^{1}\left(W_{E} ; \widehat{H}(k)\right)$. Then there is an irreducible representation $\Pi$ of $G(E)$ over $k$ such that $\rho_{\Pi} \cong{ }^{L} \psi \circ \rho_{\pi} \in \mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)$.

Proof. Choose a $\Sigma$-stable pro- $p$ compact open subgroup $K<G(E)$ such that $\pi^{\iota^{*} K} \neq 0$. From Theorem 9.3 .2 we have a commutative diagram

$$
\begin{gather*}
\text { Spec } \mathfrak{Z}\left(H, \iota^{*} K\right) \xrightarrow{\text { Spec } \mathfrak{Z}_{\mathrm{TV}}} \text { Spec } \mathfrak{Z}(G, K) \\
\downarrow^{\text {Spec } \mathrm{FS}_{H}}  \tag{9.15}\\
{\operatorname{Spec} \operatorname{Exc}_{k}\left(W_{E}, \widehat{H}\right) \xrightarrow{{ }^{L} \psi_{*}} \xrightarrow{\operatorname{Spec~FS}_{G}}}^{\text {Spec } \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)}
\end{gather*}
$$

The representation $\pi$ gives a $k$-point of Spec $\mathfrak{Z}\left(H, \iota^{*} K\right)$ lying over $\rho_{\pi}$ viewed as a $k$-point of $\operatorname{Spec} \operatorname{Exc}_{k}\left(W_{E}, \widehat{H}\right)$. The commutativity of the diagram then tells us that there is a $k$-point of $\operatorname{Spec} \mathfrak{Z}(G, K)$, say with maximal ideal $\mathfrak{m}$, lying over the $k$-point of $\operatorname{Spec} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ corresponding to ${ }^{L} \psi \circ \rho_{\pi}$.

Recall that the functor $\Pi \mapsto \Pi^{K}$ induces a bijection between irreducible admissible $G(E)$-representations with non-zero $K$-invariants and irreducible $\mathscr{H}(G, K)$-modules. It therefore suffices to construct an irreducible representation of $\mathscr{H}(G, K)$ on which the $\mathfrak{Z}(G, K)$-action factors over $\mathfrak{m}$.

By Dat-Helm-Kurinczuk-Moss DHKM, Theorem 1.1] $\mathscr{H}(G, K)$ is a finite $\mathfrak{Z}(G, K)$-module. By the ArtinTate Lemma, $\mathfrak{Z}(G, K)$ is finite over $\mathfrak{Z}(G, K)^{\sigma}$ and then $\mathscr{H}(G, K)$ is finite over $\mathfrak{Z}(G, K)^{\sigma}$. The localization of $\mathscr{H}(G, K)$ at $\mathfrak{m}$ is non-zero, since $\mathfrak{Z}(G, K) \hookrightarrow \mathscr{H}(G, K)$, so Nakayama's Lemma implies that the left $\mathscr{H}(G, K)$-module quotient $\mathscr{H}(G, K) / \mathscr{H}(G, K) \mathfrak{m}$ is finite-dimensional and non-zero. By design, it is supported over $\mathfrak{Z}(G, K) / \mathfrak{m}$, so it has an irreducible $\mathscr{H}(G, K)$-subquotient on which the $\mathfrak{Z}(G, K)$-action factors over $\mathfrak{m}$, as was to be showed.

## 10. Fargues-Scholze parameters of toral supercuspidals

In this section we will demonstrate how the preceding theory may be used to calculate the Fargues-Scholze parameters attached to explicitly constructed representations $\Pi \in D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G(E)\right)$. We will apply Theorem 9.1.1 with the automorphism $\sigma$ being conjugation by a strongly regular $\ell$-torsion element $s \in G(E)$. Then $H$ is a torus $T<G$, so the Fargues-Scholze correspondence is completely understood for $H$. Using Theorem 9.1.1, we can describe $\rho_{\Pi} \in \mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)$ in terms of $\mathrm{T}^{j}(\Pi)$ and the $\sigma$-dual homomorphism ${ }^{L} \psi$.

We will focus our attention on $\Pi \in D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G(E)\right)$ related to the "Howe-unramified toral supercuspidals" studied by Chan-Oi CO. (The method has broader scope but we regard this as a sufficiently interesting proof-of-concept for now.) Then $T$ must be taken to be an unramified elliptic torus, and we compute the
$\sigma$-dual embedding in $\$ 10.2$ it turns out to be the canonical $L$-embedding corresponding to an unramified maximal torus.

The relevant $\Pi$ arise as compact inductions of representations cut out from the cohomology of so-called "deep level Deligne-Lusztig varieties" studied by Chan-Ivanov [CI21. In $\$ 10.3$ we use equivariant localization to calculate the Tate cohomology of these deep level Deligne-Lusztig varieties. We feed the answer into 810.4 in order to compute the Tate cohomology of the compact inductions, and then tie together the calculations to describe the Fargues-Scholze parameters explicitly in Theorem 10.4.1.
10.1. Review of tori. Let $G$ be a connected reductive group over $E$.
10.1.1. The abstract Cartan. To $G$ we can associate a canonical $E$-torus $\mathbf{T}$, which we call the "abstract Cartan" of $G$. (We make no claim that $\mathbf{T}$ admits an $E$-rational embedding into $G$.) If $G$ is quasi-split, it is defined as the colimit over $E$-rational Borel subgroups $B<G$ of $B / U$, where $U$ is the unipotent radical of $B$. In general, we pass to an extension of $G$ where it becomes quasisplit, and then descend this construction.

Given an extension $E^{\prime} / E$ and a Borus $(B, T)$ over $G_{E^{\prime}}$, the composition

$$
T \hookrightarrow B \rightarrow B / U \rightarrow \mathbf{T}_{E^{\prime}}
$$

defines an isomorphism $i_{B}: T \xrightarrow{\sim} \mathbf{T}_{E^{\prime}}$.
We denote by $\mathbf{W}$ the Weyl group of $\mathbf{T}$, defined as the colimit of $N_{G_{E^{s}}}(T) / T$ over the category of Bori $(B, T)$ in $G_{E^{s}}$.
10.1.2. The cocycle of a torus. Let $T \subset G$ be a maximal torus over $E$. Over $E^{s}$, we can find a Borus $\left(B, T_{E^{s}}\right)$ inside $G_{E^{s}}$, which gives an identification $i_{B}: T_{E^{s}} \xrightarrow{\sim} \mathbf{T}_{E^{s}}$.

For $\gamma \in \operatorname{Gal}\left(E^{s} / E\right), \gamma B$ is another Borel subgroup of $G$ containing $T_{E^{s}}$, so we have another identification $i_{\gamma B}: T_{E^{s}} \xrightarrow{\sim} \mathbf{T}_{E^{s}}$.

For $\gamma \in \operatorname{Gal}\left(E^{s} / E\right)$, we denote by $\gamma_{\mathbf{T}}\left(\right.$ resp. $\left.\gamma_{T}\right)$ the endomorphism of $\mathbf{T}_{E^{s}}$ (resp. $T_{E^{s}}$ ) induced by $\gamma$. From the definition of the abstract Cartan, we see that $\gamma_{\mathbf{T}}$ is the composition

$$
\mathbf{T}_{E^{s}} \xrightarrow{i_{B}^{-1}} T_{E^{s}} \xrightarrow{\gamma_{T}} T_{E^{s}} \xrightarrow{i_{\gamma B}} \mathbf{T}_{E^{s}}
$$

For each $\gamma \in \operatorname{Gal}\left(E^{s} / E\right)$, the automorphism $i_{B} i_{\gamma B}^{-1}$ of $\mathbf{T}_{E^{s}}$ is given by an element of $\mathbf{W}$. Hence the function $z_{T, B}: \gamma \mapsto\left(i_{B} i_{\gamma B}^{-1}\right)$ defines a cocycle in $Z^{1}\left(\operatorname{Gal}\left(E^{s} / E\right) ; \mathbf{W}\right)$. Choosing a different $B$ alters $z_{T, B}$ by a coboundary, hence the cohomology class $h_{T}:=\left[z_{T, B}\right] \in \mathrm{H}^{1}\left(\operatorname{Gal}\left(E^{s} / E\right) ; \mathbf{W}\right)$ is independent of $B$. Then we have

$$
i_{B} \gamma_{T} i_{B}^{-1}=i_{B}\left(i_{\gamma B}^{-1} \gamma_{\mathbf{T}} i_{B}\right) i_{B}^{-1}=\left(i_{B} i_{\gamma B}^{-1}\right) \gamma_{\mathbf{T}}
$$

In other words, the cocycle $h_{T}$ expresses the "difference" between the $\operatorname{Gal}\left(E^{s} / E\right)$-action on $T$ and on $\mathbf{T}$.
10.1.3. The canonical L-embedding. Recall from the work of Langlands-Shelstad LS87] that given a maximal torus $T \subset G$ together with a choice of " $\chi$-data", there is a $\widehat{G}$-conjugacy class of admissible dual embeddings ${ }^{L} j:{ }^{L} T \hookrightarrow{ }^{L} G$. In general there is no distingushed choice of ${ }^{L} j$, but if $T$ is unramified then it has a distinguished choice of $\chi$-data, which gives a canonical conjugacy class of embeddings ${ }^{L} j:{ }^{L} T \rightarrow{ }^{L} G$. We will describe it more explicitly.

Using the $\widehat{G}$-conjugation, we can arrange that $\widehat{j}$ sends $\widehat{T}$ isomorphically to $\widehat{\mathbf{T}}$. Then ${ }^{L} j$ is specified by a cocycle $W_{E} \rightarrow \widehat{G}(k)$, which must land in the normalizer of $\widehat{T}$ in $\widehat{G}$, denoted $N_{\widehat{G}}(\widehat{T})(k)$. This cocycle will be chosen to lift $h_{T} \in \mathrm{H}^{1}\left(W_{E} ; \mathbf{W}\right)$. Since $T$ is unramified, all the actions factor through the unramified quotient val: $W_{E} \rightarrow\langle\varphi\rangle \cong \mathbf{Z}$, and our lift will be chosen to be inflated from $\mathrm{H}^{1}\left(\langle\varphi\rangle ; N_{\widehat{G}}(\widehat{T})(k)\right)$. The space of such liftings is controlled by an exact sequence

$$
\mathrm{H}^{1}(\langle\varphi\rangle ; \widehat{T}(k)) \rightarrow \mathrm{H}^{1}\left(\langle\varphi\rangle ; N_{\widehat{G}}(\widehat{T})(k)\right) \rightarrow \mathrm{H}^{1}(\langle\varphi\rangle ; \mathbf{W}) .
$$

We will explicate the correct lift only in the case that $T$ is elliptic, i.e., anisotropic mod center.
First suppose $G$ is semi-simple: then $T$ is anisotropic, so that

$$
\mathrm{H}^{1}(\langle\varphi\rangle ; \widehat{T}(k))=\widehat{T}(k) / \varphi-\operatorname{conj}=\{1\}
$$

hence ${ }^{L} j$ is uniquely determined in this case by the condition of lifting $h_{T}$.

In general, consider the adjoint quotient $G \rightarrow G_{\mathrm{ad}}$. Let $\bar{T}:=T / Z(G)$, so we have a pullback square

On the dual side we have $\widehat{G_{\text {ad }}} \rightarrow \widehat{G}$ and $\widehat{\bar{T}} \rightarrow \widehat{T}$, forming a pushout square

Let ${ }^{L} j_{\mathrm{ad}}:{ }^{L} \bar{T} \rightarrow{ }^{L} G_{\text {ad }}$ be the $L$-embedding specified in the preceding paragraph. Then from DR09, §4.3], one sees that ${ }^{L} j$ is the pushout of ${ }^{L} j_{\text {ad }}$, as in the following pushout square:

10.2. Calculation of the $\sigma$-dual homomorphism. Let $T \subset G$ be an unramified elliptic maximal torus defined over $E$.

Proposition 10.2.1. Suppose $T(E)$ contains an element $s$ of order $\ell$ which maps to a strongly regular element of $G_{\mathrm{ad}}(E)$. Let $\sigma=\operatorname{conj}_{s}$ be the conjugation action of $s$ on $G$, so $G^{\sigma}=T$. Assume $\ell>b(\breve{G})$. Then the $\sigma$-dual homomorphism ${ }^{L} \psi:{ }^{L} T \rightarrow{ }^{L} G$ lies in the $\widehat{G}$-conjugacy class of the composition

$$
{ }^{L} T \xrightarrow{\mathrm{Fr}_{\ell}}{ }^{L} T \xrightarrow{L_{j}}{ }^{L} G .
$$

where $\mathrm{Fr}_{\ell}$ is induced by the Frobenius endomorphism $\check{T} \rightarrow \check{T}$ (corresponding to multiplication by $\ell$ on character groups).

We begin with some preliminaries before turning to the proof. Any choice of $B \supset T_{E^{s}}$ gives a commutative diagram

By Lemma 7.5.2 and Corollary 7.6.7. diagram 10.1 induces an isomorphism

$$
\begin{equation*}
b r \cong\left(\operatorname{Fr}_{\ell}\right)^{*} i_{B}^{*} \mathrm{CT}_{B}: \operatorname{Rep}_{k}(\widehat{G}) \rightarrow \operatorname{Rep}_{k}(\widehat{T}) \tag{10.2}
\end{equation*}
$$

Thus the choice of $B$ gives an identification $\widehat{i}_{B}^{-1}: \widehat{T} \xrightarrow{\sim} \widehat{\mathbf{T}}$ in such a way that the map $\check{\psi}$, the restriction of ${ }^{L} \psi$ to the identity component, factors as in the diagram below
where $\check{\phi}_{B}$ is $\widehat{i}_{B}^{-1}$ composed with the Frobenius endomorphism $\operatorname{Fr}_{\ell}$ of $\widehat{T}$. As discussed in $\$ 10.1 .2$, the map $\widehat{i}_{B}$ carries the $W_{E}$-action on $\check{T}$ to the $W_{E}$-action on $\widehat{\mathbf{T}}$ twisted by the cocycle $h_{T}$, so for all $\gamma \in W_{E}$ we have

$$
\begin{equation*}
\check{\psi} \circ \gamma_{\widehat{T}}=h_{T}(\gamma) \cdot\left(\gamma_{\widehat{\mathbf{T}}} \circ \check{\phi}_{B}\right) \tag{10.4}
\end{equation*}
$$

This has the following consequence. The map 10.2 carries $W_{E} \subset{ }^{L} T$ to $N_{\widehat{G}}(\widehat{\mathbf{T}}) \rtimes W_{E}$, so its projection to the first component defines a class $\operatorname{pr}_{1}\left({ }^{L} \psi\right) \in \mathrm{H}^{1}\left(W_{E} ; N_{\widehat{G}}(\widehat{\mathbf{T}})\right)$. Denote by $\left[\mathrm{pr}_{1}\left({ }^{L} \psi\right)\right] \in \mathrm{H}^{1}\left(W_{E} ; \mathbf{W}\right)$ the projection of $\operatorname{pr}_{1}\left({ }^{L} \psi\right)$ along $N_{\breve{G}}(\check{\mathbf{T}}) \rightarrow \mathbf{W}$. From 10.4 we conclude:
Lemma 10.2.2. We have $h_{T}=\left[\operatorname{pr}_{1}\left({ }^{L} \psi\right)\right] \in \mathrm{H}^{1}\left(W_{E} ; \mathbf{W}\right)$.

As explained in $\S 10.1 .3$ Lemma 10.2 .2 already shows that Proposition 10.2 .1 holds if $G$ is semi-simple and $T$ is an elliptic unramified torus. For the general case, note that by hypothesis $s$ maps to a strongly regular element $s \in G_{\text {ad }}$ of order $\ell$, whose centralizer is $\bar{T}$, so a similar theory applies to $G_{\text {ad }}$. This induces a functor

$$
\tilde{b r}_{\mathrm{ad}}: \operatorname{Sat}\left(\operatorname{Gr}_{G_{\mathrm{ad}}, \operatorname{Div}_{X}^{1}} ; k\right) \rightarrow \operatorname{Sat}\left(\operatorname{Gr}_{\bar{T}, \operatorname{Div}_{X}^{1}} ; k\right)
$$

and we study its relation to the functor

$$
\widetilde{b r}: \operatorname{Sat}\left(\operatorname{Gr}_{G, \operatorname{Div}_{X}^{1}} ; k\right) \rightarrow \operatorname{Sat}\left(\operatorname{Gr}_{T, \operatorname{Div}_{X}^{1}} ; k\right)
$$

which corresponds under Geometric Satake to ${ }^{L} \psi$.
We record some general properties of the Geometric Satake equivalence. If $G \rightarrow G^{\prime}$ is a central isogeny, then the induced map $f: \mathrm{Gr}_{G, \operatorname{Div}_{X}^{1}} \rightarrow \mathrm{Gr}_{G^{\prime}, \operatorname{Div}_{X}^{1}}$ restricts to isomorphisms of connected components, and the restriction map $\operatorname{Rep}_{k}\left({ }^{L} G^{\prime}\right) \rightarrow \operatorname{Rep}_{k}\left({ }^{L} G\right)$ is intertwined under Geometric Satake with the (derived) pushforward functor

$$
\begin{equation*}
\operatorname{Sat}\left(\mathrm{Gr}_{G, \operatorname{Div}_{X}^{1}} ; k\right) \xrightarrow{\mathrm{R} f_{*}} \operatorname{Sat}\left(\mathrm{Gr}_{G^{\prime}, \operatorname{Div}_{X}^{1}} ; k\right) . \tag{10.5}
\end{equation*}
$$

We record the following general property of the Brauer functor.
Lemma 10.2.3. Assume $\ell>\max \{b(\check{G}), b(\check{H})\}$. Write $\bar{H}:=H /(H \cap Z(G))$ and assume that $\bar{H}=\left(G_{\text {ad }}\right)^{\sigma}$. Then the diagram

commutes, where the horizontal maps are of the form 10.5.
Proof. Write $f: \operatorname{Gr}_{H, S / \operatorname{Div}_{X}^{1}} \rightarrow \operatorname{Gr}_{\bar{H}, S / \operatorname{Div}_{X}^{1}}$ and $g: \operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} \rightarrow \operatorname{Gr}_{G_{\text {ad }}, S / \operatorname{Div}_{X}^{1}}$ for the projections induced by the quotients by $Z(G)$. By construction of $\widetilde{b r}$ and $\widetilde{b r}_{\mathrm{ad}}$, it suffices to show that the diagram

$$
\begin{gather*}
\operatorname{Par}^{\mathrm{ULA}}\left(\mathrm{Gr}_{\bar{H}, S / \operatorname{Div}_{X}^{1}} ; k\right) \stackrel{\mathrm{R} f_{*}}{\Vdash} \operatorname{Par}^{\mathrm{ULA}}\left(\mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} ; k\right) \\
\operatorname{br}_{\mathrm{ad}} \uparrow  \tag{10.7}\\
\operatorname{Par}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G_{\mathrm{ad}}, S / \operatorname{Div}_{X}^{1}} ; k\right) \stackrel{\mathrm{R} g_{*}}{\longleftarrow} \operatorname{Par}^{\mathrm{ULA}}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right)
\end{gather*}
$$

commutes for any strictly totally disconnected $S$ over $\operatorname{Div}_{X}^{1}$.
Let $\mathcal{F} \in \operatorname{Par}^{U L A}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; \mathbb{O}\right)$ and $\mathbb{F} \mathcal{F}:=\mathcal{F} \otimes_{\mathbb{O}} k \in \operatorname{Par}^{U L A}\left(\operatorname{Gr}_{G, S / \operatorname{Div}_{X}^{1}} ; k\right)$. Then we have natural isomorphisms

$$
\begin{aligned}
\mathrm{R} f_{*} \circ b r(\mathbb{F} \mathcal{F}) & =\mathrm{R} f_{*} \circ L \circ\left[\dagger_{H}^{G}\right] \circ \operatorname{Psm} \circ \mathrm{Nm}^{\left(\ell^{-1}\right)}(\mathbb{F} \mathcal{F}) \\
& \stackrel{(1)}{\cong} L \circ \mathrm{R} f_{*} \circ\left[\dagger_{H}^{G}\right] \circ \operatorname{Psm} \circ \mathrm{Nm}^{\left(\ell^{-1}\right)}(\mathbb{F} \mathcal{F}) \\
& \stackrel{(2)}{\cong} L \circ\left[\dagger \frac{G_{\mathrm{ad}}}{H}\right] \circ \mathrm{R} f_{*} \circ \operatorname{Psm} \circ \mathrm{Nm}^{\left(\ell^{-1}\right)}(\mathbb{F} \mathcal{F}) \\
& \stackrel{(3)}{\cong} L \circ\left[\dagger \frac{G_{\mathrm{ad}}}{H}\right] \circ \operatorname{Psm} \circ \mathrm{R}_{*} \circ \mathrm{Nm}^{\left(\ell^{-1}\right)}(\mathbb{F} \mathcal{F}) \\
& \stackrel{(4)}{\cong} L \circ\left[\dagger \dagger_{\mathrm{ad}}^{H}\right] \circ \operatorname{Psm} \circ \mathrm{Nm}^{\left(\ell^{-1}\right)} \circ \mathrm{R} g_{*}(\mathbb{F} \mathcal{F}) \\
& =b r_{\mathrm{ad}} \circ \mathrm{R} g_{*}(\mathbb{F} \mathcal{F})
\end{aligned}
$$

whose composition gives the desired commutativity. Here, the natural isomorphisms are justified as follows:
(1) is evident from the fact that $\mathrm{R} f_{*}$ preserves normalized parity sheaves, because $f$ restricts to an isomorphism between connected components of the source and target.
(2) holds because $G$ and $G_{\text {ad }}$ differ by a central quotient, and similarly for $H$ and $\bar{H}$, so $\left[\dagger_{H}^{G}\right]=\left[\dagger \frac{G_{\text {ad }}}{H}\right]$; and clearly shifts commute with $\mathrm{R} f_{*}$.
(3) holds by Proposition 5.2.10, using Proposition 4.1.2 to see that applying $\Sigma$-fixed points to the map $g: \mathrm{Gr}_{G, S / \operatorname{Div}_{X}^{1}} \rightarrow \mathrm{Gr}_{G_{\text {ad }}, S / \operatorname{Div}_{X}^{1}}$ yields $f: \mathrm{Gr}_{H, S / \operatorname{Div}_{X}^{1}} \rightarrow \operatorname{Gr}_{\bar{H}, S / \operatorname{Div}_{X}^{1}}$.
(4) holds because $\mathrm{R} g_{*}$ is symmetric monoidal.

Proof of Proposition 10.2.1. Combining Lemma 10.2 .3 with Tannakian reconstruction, we find that the diagram

commutes. As mentioned above, Corollary 7.6.7 implies that it factors as

By inspection the bottom square induces isomorphism on the cokernels of the rows, hence is a pushout square. As explained in $\S 10.1 .3$ Lemma 10.2 .2 implies that $\zeta_{\text {ad }}$ is $\widehat{G}$-conjugate to the canonical ${ }^{L} j_{\text {ad }}$. Since $\zeta$ is pushed out from $\zeta_{\mathrm{ad}}$ and ${ }^{L} j$ is pushed out from ${ }^{L} j_{\mathrm{ad}}$, we deduce that $\zeta$ is $\widehat{G}$-conjugate to ${ }^{L} j$, and then that ${ }^{L} \psi$ is $\check{G}$-conjugate to ${ }^{L} j \circ \mathrm{Fr}_{\ell}$, as desired.
10.3. Tate cohomology of deep level Deligne-Lusztig varieties. We briefly recall the generalized Deligne-Lusztig representations appearing in CI21.
10.3.1. Group-theoretic setup. Let $T \hookrightarrow G$ be an unramified maximal torus and $x \in \mathcal{B}(G / E)$ be a point of the Bruhat-Tits building of $G$ that lies in the apartment of $T$. Corresponding to $x$ we have by Bruhat-Tits theory a parahoric group scheme $\mathcal{G} / \mathcal{O}_{E}$, whose generic fiber is $G / E$.

Recall that $\mathbf{F}_{q}$ is the residue field of $E$. By assumption, $T$ splits over $\breve{E}$. Choose a $\breve{E}$-rational Borel subgroup of $G_{\breve{E}}$ containing $T_{\breve{E}}$, and let $U$ be its unipotent radical.

For $r \in \mathbf{Z}_{\geq 0}$, we have group schemes $\mathbb{G}_{r}, \mathbb{T}_{r}$ over $\mathbf{F}_{q}$ as in $[\mathbf{C O}, \S 6.1]^{7}$ corresponding to subquotients of the Moy-Prasad filtration at $x$, such that

$$
\mathbb{G}_{r}\left(\mathbf{F}_{q}\right)=G_{x, 0: r+}:=G_{x, 0} / G_{x, r+} \quad \text { and } \quad \mathbb{T}_{r}\left(\mathbf{F}_{q}\right)=T_{0: r+}:=T_{x, 0} / T_{x, r+}
$$

We also have a group scheme $\mathbb{U}_{r} \subset\left(\mathbb{G}_{r}\right)_{\overline{\mathbf{F}}_{q}}$ corresponding to $U$.
10.3.2. Deep level Deligne-Lusztig varieties. Let $\operatorname{Fr}_{q}$ be the $q$-power Frobenius for schemes over $\mathbf{F}_{q}$. We recall certain schemes constructed in [CI21, §4]: the "deep level Deligne-Lusztig varieties"

$$
S_{\mathbb{T}_{r}, \mathbb{U}_{r}}:=\left\{x \in\left(\mathbb{G}_{r}\right)_{\overline{\mathbf{F}}_{q}}: x^{-1} \mathrm{Fr}_{q}(x) \in \mathbb{U}_{r}\right\} .
$$

(The variety $S_{\mathbb{T}_{r}, \mathbb{U}_{r}}$ is called $X_{r}$ in CO.) It is a separated, smooth, finite type scheme over $\overline{\mathbf{F}}_{q}$, with an action of $\mathbb{G}_{r}\left(\mathbf{F}_{q}\right) \times \mathbb{T}_{r}\left(\mathbf{F}_{q}\right)$ by multiplication on the left and right. The action of $\mathbb{T}_{r}\left(\mathbf{F}_{q}\right)$ is free, and we define

$$
X_{\mathbb{T}_{r}, \mathbb{U}_{r}}:=S_{\mathbb{T}_{r}, \mathbb{U}_{r}} / \mathbb{T}_{r}\left(\mathbf{F}_{q}\right)
$$

Example 10.3.1. When $r=0$, the definition of $X_{\mathbb{T}_{r}, \mathbb{U}_{r}}$ specializes to that of a classical Deligne-Lusztig variety DL76.
Definition 10.3.2 (Deep level Deligne-Lusztig induction). Let $\theta: \mathbb{T}_{r}\left(\mathbf{F}_{q}\right) \rightarrow k^{\times}$be a character. Let $\mathcal{L}_{\theta}$ be the corresponding local system on $X_{\mathbb{T}_{r}, \mathbb{U}_{r}}$. We define

$$
R_{\mathbb{T}_{r}, \mathbb{U}_{r}}^{\mathbb{G}_{r}}(\theta):=\mathrm{R} \Gamma_{c}^{*}\left(X_{\mathbb{T}_{r}, \mathbb{U}_{r}} ; \mathcal{L}_{\theta}\right) \in D^{b}\left(\operatorname{Rep}_{k} \mathbb{G}_{r}\left(\mathbf{F}_{q}\right)\right)
$$

[^6]10.3.3. Calculation of Tate cohomology. Following CI21, §2.8], we define $W_{x}(T)$ to be the subgroup of $W(T, G)$ generated by vector parts of affine roots $\psi$ of $G$ for which $\psi(x)=0$.

Following CI21, Definition 5.1], we say that $s \in G_{x}\left(\mathcal{O}_{\breve{E}}\right)$ is unramified very regular (with respect to $x$ ) if $s$ is regular semisimple in $G_{\breve{E}}$, its connected centralizer $Z_{G}^{\circ}(s)$ is an $\breve{E}$-split maximal torus of $G_{\breve{E}}$, and $\alpha(s) \not \equiv 1\left(\bmod \varpi_{E}\right)$ for all roots $\alpha$ of $Z_{G}^{\circ}(s)$. We say that $s \in \mathbb{G}_{r}\left(\overline{\mathbf{F}}_{q}\right)$ is unramified very regular if it is the image of an unramified very regular element of $G_{x}\left(\mathcal{O}_{\breve{E}}\right)$.

Proposition 10.3.3. Let $s \in \mathbb{T}_{r}\left(\mathbf{F}_{q}\right)$ be unramified very regular in $\mathbb{G}_{r}\left(\overline{\mathbf{F}}_{q}\right)$ and of order $\ell$, and let $\sigma=\operatorname{conj}_{s}$ as an automorphism of $G$. Then for each $j \in \mathbf{Z} / 2 \mathbf{Z}$ we have

$$
\begin{equation*}
\mathrm{T}^{j}\left(R_{\mathbb{T}_{r}, \mathbb{U}_{r}}^{\mathbb{G}_{r}}(\theta)\right) \cong \bigoplus_{w \in W_{x}(T)^{\mathrm{Fr}_{q}}} \theta^{w} \in D^{b}\left(\operatorname{Rep}_{k} \mathbb{T}_{r}\left(\mathbf{F}_{q}\right)\right) \tag{10.8}
\end{equation*}
$$

where $\theta^{w}=\theta \circ w^{-1}$ is the translate of $\theta$ by the action of $w$.
Proof. By CI21, Proposition 5.6], we have

$$
\begin{equation*}
\operatorname{Fix}\left(\sigma, X_{\mathbb{T}_{r}, \mathbb{U}_{r}}\right)=\bigcup_{w \in W_{x}(T)^{\mathrm{Fr}_{q}}}[\dot{w}] \tag{10.9}
\end{equation*}
$$

where $[\dot{w}]$ is the coset $\dot{w} \mathbb{T}_{r}\left(\mathbf{F}_{q}\right)$ of any lift $\dot{w} \in \mathbb{G}_{r}\left(\overline{\mathbf{F}}_{q}\right)$ of $w$.
By [Fen, §A.1.2] (which is the scheme-theoretic counterpart to 55.2 .3 ), this implies that

$$
\mathrm{T}^{j}\left(R_{\mathbb{T}_{r}, \mathbb{U}_{r}}^{\mathbb{G}_{r}}(\theta)\right)=\left.\mathrm{T}^{j}\left(\mathrm{R} \Gamma_{c}^{*}\left(X_{\mathbb{T}_{r}, \mathbb{U}_{r}} ; \mathcal{L}_{\theta}\right)\right) \cong \mathrm{T}^{j}\left(\bigcup_{w \in W_{x}(T)^{\mathrm{Fr} q}}[\dot{w}] ; \mathcal{L}_{\theta}\right) \cong \bigoplus_{w \in W_{x}(T)^{\mathrm{Fr} q}} \mathcal{L}_{\theta}\right|_{[\dot{w}]} .
$$

Here $\left.\mathcal{L}\right|_{[\dot{w}]}$ is a $\mathbb{T}_{r}\left(\mathbf{F}_{q}\right)$-equivariant sheaf on a point, i.e., a representation of $\mathbb{T}_{r}\left(\mathbf{F}_{q}\right)$. Writing $t \dot{w}=\dot{w}\left(\dot{w}^{-1} t \dot{w}\right)$, we see that $\left.\mathcal{L}_{\theta}\right|_{[\dot{w}]} \cong \theta^{w} \in \operatorname{Rep}_{k} \mathbb{T}_{r}\left(\mathbf{F}_{q}\right)$.
10.4. Howe-unramified toral representations. We may regard $R_{\mathbb{T}_{r}, \mathbb{U}_{r}}^{\mathbb{G}_{r}}(\theta)$ as a (derived) smooth representation of $G_{x, 0}$ by inflation. Choose some extension of $\theta$ to $T(E)$, which we use to regard $R_{\mathbb{T}_{r}, \mathbb{U}_{r}}^{\mathbb{G}_{r}}(\theta)$ as a (derived) smooth representation of $T(E) G_{x, 0}$. Then we define

$$
\pi_{T, U, \theta}:=\operatorname{c-} \operatorname{Ind}_{T(E) G_{x, 0}}^{G(E)} R_{\mathbb{T}_{r}, \mathbb{U}_{r}}^{\mathbb{G}_{r}}(\theta) \in D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G(E)\right)
$$

Note that since $\sigma$ is inner, Example 9.1 .3 applies to equip any $\Pi \in D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G(E)\right)$ with a canonical $\Sigma$-equivariant structure. In particular, we use this to view $\pi_{T, U, \theta} \in D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}} G(E)\right)^{B \Sigma}$.

In preparation for calculating the Tate cohomology of $\pi_{T, U, \theta}$, we study the interaction between compact induction and Tate cohomology. Let $K \subset G(E)$ be any $\Sigma$-stable closed subgroup. Let $Y:=G(E) / K$. Then there is a functor from finite-dimensional representations of $K$ to $G(E)$-equivariant local systems on $Y$, which we denote $V \mapsto \mathcal{F}(V)$. In turn, there is a functor from $G(E)$-equivariant local systems on $Y$ to smooth $G(E)$-representations, obtained by taking compactly supported global sections. Assuming that $K$ is open, the composite functor

$$
V \mapsto \mathrm{R}_{c}(Y ; \mathcal{F}(V))
$$

is the compact induction from $K$ to $G(E)$. By [TV16, §3.3] we have for each $j \in \mathbf{Z} / 2 \mathbf{Z}$ a natural isomorphism

$$
\begin{equation*}
\mathrm{T}^{j}\left(\mathrm{R} \Gamma_{c}(Y ; \mathcal{F})\right) \cong \mathrm{T}^{j}\left(\mathrm{R} \Gamma_{c}\left(Y^{\sigma} ; \mathcal{F}\right)\right) \in \operatorname{Rep}_{k}^{\mathrm{sm}} H(E) \tag{10.10}
\end{equation*}
$$

for any $G(E)$-equivariant local system $\mathcal{F}$ on $Y$.
Theorem 10.4.1. Let $T<G$ be an elliptic unramified maximal torus. Assume that $T(E)$ contains an element $s$ of order $\ell$, which is unramified very regular with respect to $x \in \mathcal{B}(G / E)$ and strongly regular in $G_{\mathrm{ad}}(E)$. Then for any $\theta: T(E) \rightarrow k^{\times}$, $\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)}\left(\mathrm{H}^{*}\left(\pi_{T, U, \theta}\right)\right)$ contains the point of $\operatorname{Spec} \operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ corresponding to the semi-simple L-parameter

$$
\begin{equation*}
W_{E} \xrightarrow{L_{\theta}}{ }^{L} T(k) \xrightarrow{L_{j}}{ }^{L} G(k) \tag{10.11}
\end{equation*}
$$

where ${ }^{L} \theta$ is the $L$-parameter given by class field theory, and ${ }^{L} j$ is canonical L-embedding of $T$ ( 10.1.3).

Proof. Let $\sigma \in \operatorname{Aut}(G)$ by the conjugation by $s$, so $G^{\sigma}=T$. Note that the hypotheses on $s$ imply that Proposition 10.2 .1 holds in this situation.

Let $K=T(E) G_{x, 0}$. Since $T$ is elliptic, we have $K=Z_{G} G_{x, 0}$ where $Z_{G}$ is the center of $G(E)$. Note that $\mathrm{H}^{1}(\Sigma ; K)$ is finite, as it has a finite-index subgroup of the form $Z_{G}$ times a pro-p subgroup and $p \neq l=|\Sigma|$. From the long exact sequence in non-abelian cohomology

$$
1 \rightarrow K^{\sigma} \rightarrow G(E)^{\sigma} \rightarrow(G(E) / K)^{\sigma} \rightarrow \mathrm{H}^{1}(\Sigma ; K) \rightarrow \mathrm{H}^{1}(\Sigma ; G(E))
$$

and the torsor-shifting discussion in [Ser94, §5.3, 5.4], we see that

$$
(G(E) / K)^{\sigma}=\bigcup_{\xi \in \operatorname{ker}\left[\mathrm{H}^{1}(\Sigma ; K) \rightarrow \mathrm{H}^{1}(\Sigma ; G(E))\right]} G(E) /\left({ }_{\xi} K\right)^{\sigma}
$$

where ${ }_{\xi} K$ is the twist of $K$ corresponding to the torsor $\xi$. Henceforth we abbreviate

$$
\operatorname{ker}^{1}(\Sigma ; K, G):=\operatorname{ker}\left[\mathrm{H}^{1}(\Sigma ; K) \rightarrow \mathrm{H}^{1}(\Sigma ; G(E))\right]
$$

Since $\left({ }_{\xi} K\right)^{\sigma} \supset\left({ }_{\xi} T\right)^{\sigma}=T$, we see that each $G(E)^{\sigma} /\left({ }_{\xi} K\right)^{\sigma}$ is a point, which we will denote $[\xi] \in(G(E) / K)^{\sigma}$. From 10.10 we get, for each $j \in \mathbf{Z} / 2 \mathbf{Z}$, an equivariant isomorphism

$$
\mathrm{T}^{j}\left(\pi_{T, U, \theta}\right) \cong \bigoplus_{\xi \in \operatorname{ker}^{1}(\Sigma ; K, G)} \mathrm{T}^{j}\left(\mathcal{F}\left(R_{\mathbb{T}_{r}, \mathbb{U}_{r}}^{\mathbb{G}_{r}}(\theta)\right)_{[\xi]}\right) \in D^{b}\left(\operatorname{Rep}_{k}^{\mathrm{sm}} T(E)\right)
$$

In particular, taking $\xi=1 \in \mathrm{H}^{1}(\Sigma ; K)$ to the trivial class, we see that from Proposition 10.3 .3 that a direct sum of Weyl conjugates of $\theta$ appears as a direct summand of $\mathrm{T}^{j}\left(\pi_{T, U, \theta}\right)$, as a representation of $T(E)$.

By Theorem 9.1.1. we deduce that $F_{*} \operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)}\left(\pi_{T, U, \theta)}\right)$ contains the image under ${ }^{L} \psi \operatorname{of~}^{\operatorname{supp}} \operatorname{Exc}_{k}\left(W_{E}, \widehat{T}\right)=\theta^{w}$ for various $w \in W(T, G)$. For tori, the Fargues-Scholze correspondence is known to be compatible with the usual Local Langlands Correspondence, $\operatorname{so~}_{\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{T}\right)} \theta^{w} \text { is the point corresponding to the } L \text {-parameter }}$ of class field theory

$$
\begin{equation*}
W_{E} \xrightarrow{L_{\theta^{w}}}{ }^{L} T(k) \tag{10.12}
\end{equation*}
$$

Note that ${ }^{L} \psi \circ{ }^{L} \theta^{w}={ }^{L} \psi \circ{ }^{L} \theta \in \mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)$ for each $w \in W$, since the Weyl conjugation becomes inner in $\widehat{G}$.

By Proposition 10.2.1 we have

$$
{ }^{L} \psi \circ{ }^{L} \theta={ }^{L} j \circ \operatorname{Fr}_{\ell} \circ{ }^{L} \theta=\operatorname{Fr}_{\ell} \circ{ }^{L} j \circ{ }^{L} \theta \in \mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)
$$

so we deduce that $F_{*} \operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)}\left(\pi_{T, U, \theta}\right)$ contains $\operatorname{Fr}_{\ell} \circ^{L} j \circ{ }^{L} \theta$. By inspection of the definition, Frobenius (un)twisting is compatible with the Fargues-Scholze correspondence in the sense that

$$
\begin{equation*}
F_{*} \operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)} \Pi=\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)} F_{*} \Pi=\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)} \Pi^{(\ell)} \tag{10.13}
\end{equation*}
$$

so $\operatorname{supp}_{\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)}\left(\pi_{T, U, \theta}\right)$ contains the point of $\operatorname{Exc}_{k}\left(W_{E}, \widehat{G}\right)$ corresponding to ${ }^{L} j \circ{ }^{L} \theta \in \mathrm{H}^{1}\left(W_{E} ; \widehat{G}(k)\right)$, as desired.

Corollary 10.4.2. There is a non-zero irreducible $G(E)$-subquotient $\Pi$ of $\mathrm{H}^{i}\left(\pi_{T, U, \theta}\right)$, for some $i$, such that $\rho_{\Pi}$ is 10.11 . In particular, if $\pi_{T, U, \theta}$ is concentrated in a single cohomological degree and is irreducible, then its Fargues-Scholze parameter is 10.11.

Remark 10.4.3. Note that Theorem 10.4 .1 imposes no regularity conditions on $\theta$. We expect that if $\theta$ is sufficiently regular, and $\ell$ is not too small, then $\pi_{T, U, \theta}$ should be concentrated in a single cohomological degree and irreducible, and cuspidal. There are interesting classes of examples where this is known; a notable one pertains to the depth-zero supercuspidals [DR09], which correspond to the case where:

- $x \in \mathcal{B}(G / E)$ is a vertex (so $G_{x}$ is a maximal parahoric),
- $r=0$, so $X_{\mathbb{T}_{0}, \mathbb{U}_{0}}$ is a usual Deligne-Lusztig variety,
- $T$ is not contained in a proper parabolic subgroup and $\theta$ is non-singular (meaning that it is not orthogonal to any coroot, cf. [DL76, Definition 5.15(1)]), so its Deligne-Lusztig induction is cuspidal. Letting $\mathcal{L}_{\theta}$ be the character sheaf on $X_{\mathbb{T}_{0}, \mathbb{U}_{0}}$ associated with the non-singular character $\theta: T\left(\mathbf{F}_{q}\right) \rightarrow k^{\times}$, it follows from [DL76, Lemma 9.14] and [Bro90, Lemma 3.5] that in this situation $\mathrm{H}_{c}^{*}\left(X_{\mathbb{T}_{0}, \mathbb{U}_{0}} ; \mathcal{L}_{\theta}\right)$ concentrates in a single degree; and if the prime-to- $\ell$ component of $\theta$ is in general position then $\mathrm{H}_{c}^{*}\left(X_{\mathbb{T}_{0}, U_{0}} ; \mathcal{L}_{\theta}\right)$ is irreducible by Bro90, Lemma 3.6].

[Zhu21] Xinwen Zhu, A note on Integral Satake isomorphisms, 2021.

[^0]:    ${ }^{1}$ A subtle but important point found by Treumann-Venkatesh is that, when taking into account the full $L$-group, a $\sigma$-dual homomorphism may not exist with the "usual" notion of $L$-group due to Langlands. Treumann-Venkatesh suggest in TV14, $\S 7.8]$ that this problem might be repaired by instead using the " $c$-group", which is the variant of the $L$-group that naturally comes out of the geometric Satake equivalence Zhu17, Remark 5.5.11]. For non-archimedean local fields there is actually an isomorphism between the $L$-group and the $c$-group (possibly depending on choice of square root of $p$ in $k$ ), so this distinction is not essential for our purposes, but it seems to support the morality of our approach.

[^1]:    ${ }^{2}$ Explicitly, this means that $\ell>2$ if $\breve{G}$ has simple factors of type $B, C$ or $D ; \ell>3$ if $\widehat{G}$ has simple factors of type $G_{2}, F_{4}, E_{6}, E_{7}$; and $\ell>5$ if $\widehat{G}$ has simple factors of type $E_{8}$.

[^2]:    ${ }^{3}$ So $A=\underline{\lim } A_{i}$, which we note is already complete since any Cauchy sequence already lies in some $A_{i}$ by the $\omega_{1}$-cofiltered condition.

[^3]:    ${ }^{4}$ Although we will only apply this Lemma in the case where $A$ is commutative.

[^4]:    ${ }^{5}$ Our argument uses $\Lambda=k$, but the assertions may be true in greater generality, as far as we know.

[^5]:    ${ }^{6}$ Using also that $Y^{\sigma} \hookrightarrow Y$ is $\omega_{0}$-locally extra small (cf. Example 3.1.4.

[^6]:    ${ }^{7}$ The indexing seems to differ from that of CI21 §2.5, 2.6] by 1.
