#### Softwares

Two software tools:  ${\bf ppsc-soe}$  and  ${\bf adapol}$  .

- 1. ppsc-soe
  - Pseudo-particle self-consistent calculations via sum-of-exponentials.
  - ▶ Fast, *deterministic*, and **parallel** impurity solver.
  - ▶ Written in C++, with a Python interface, compatible with TRIQS.
- 2. adapol
  - ► Adaptive pole fitting for Matsubara functions.
  - ▶ Applications: bath fitting in DMFT, analytic continuation.

# A shared ingredient of both softwares are *sum-of-exponentials approximation* of the Matsubara functions, also known as the *pole fitting* problem.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三回 のへぐ

#### Pole fitting of Matsubara functions

We'd like to find an approximation to  $G(i\nu_k)$  in the following form:

$$G(\mathrm{i}\nu_k) \approx \sum_{j=1}^p \frac{W_j}{\mathrm{i}\nu_k - \lambda_j}, \quad \forall k \in \mathbb{Z}.$$

Here  $\lambda_j$  are the poles, and  $W_j$  are the weight matrices  $(n \times n)$ . This is equivalent to the following approximation to  $G(\tau)$ :

$$G(\tau) \approx -\sum_{j=1}^{p} \widetilde{W}_{j} \mathrm{e}^{-\lambda_{j}\tau}, \quad \forall \tau \in [0, \beta].$$

Here  $\widetilde{W}_j = \frac{W_j}{1 \mp e^{-\beta E}}$ . We hope that the number of terms p is as small as possible.

## Fewer poles than DLR?

- ► Let spectral width  $\leq \Lambda$ . Given  $\beta\Lambda$  and accuracy  $\varepsilon$ , DLR provides a **basis** of exponentials for **all** Green's functions.
- ▶ Why do we want another pole fitting method?
- If we only need poles for a specific  $G(\tau)$ , could we find a more compact basis (poles)?
- ▶ The answer is YES!

# AAA algorithm<sup>1</sup> for rational approximation

Barycentric formula for rational interpolants ( $z \in \mathbb{C}$ ):

$$f(z) = p(z)/q(z) = \left(\sum_{l=1}^{m} \frac{w_l f_l}{z - z_l}\right) / \left(\sum_{l=1}^{m} \frac{w_l}{z - z_l}\right)$$

This satisfies  $f(z_j) = f_j$  automatically at support points  $z_j$ . AAA algorithm: an **iterative** procedure that selects the next support point in a **greedy** fashion. At the *j*-th iteration:

- Select the next sample point  $z_j$ , at which the error of the current barycentric approximant is maximal.
- ▶ Choose  $w_l$ 's by minimizing  $\sum_{z \neq z_j} |f(z)q(z) p(z)|^2$ . This is a linear problem and boils down to compute an SVD.
- ► Continue until desired accuracy.

The poles of f(z) are the zeros of q(z). This reduces to a polynomial root finding problem.

<sup>&</sup>lt;sup>1</sup>Nakatsukasa, Yuji, Olivier Sète, and Lloyd N. Trefethen. "The AAA algorithm for rational approximation." SIAM Journal on Scientific Computing 40.3 (2018): (A1494-A1522.

#### Pole fitting procedure

Given  $i\nu_j$  and  $G(i\nu_j)$ ,

Step 1: Use AAA algorithm to obtain poles  $\{\lambda_k\}_{k=1}^p$ .

Step 2: Obtain weights  $W_j$  using linear least square fitting.

$$\min_{W_j} \sum_k \left\| G(i\nu_k) - \sum_{j=1}^p \frac{W_j}{i\nu_k - \lambda_j} \right\|^2$$

Note that this is a linear least squares problem with respect to  $W_j$ . (But not linear for the poles  $\lambda_j$ ).

Step 3: (optional) postprocessing: further refinement of the poles using bilevel optimizations.

# Application: bath fitting

- In (equilibrium) DMFT with Hamitonian-based impurity solvers, bath fitting is a crucial subroutine for the self-consistent iterations.
- Given  $\Delta(iw)$ , we want to obtain a fitting in the following form:

$$\Delta(\mathrm{i}w) \approx \sum_{k=1}^{N_b} \frac{V_k V_k^{\dagger}}{\mathrm{i}w - \omega_k}.$$

- This could be achieved via pole fitting +semidefinite programming (SDP) + bilevel optimization.
- Also applicable to the problem of analytic continuation <sup>2</sup>, especially for noisy data.

# Application: fast diagram evaluation

- Using the same setting as in H. U. R. Strand's previous talk: strong coupling expansion and pseudo-particle representation as an example.
- ▶ The most time-consuming part is to calculate the self-energy Feynman diagrams and single-particle Green's functions Feynman diagrams.

うして ふゆ く 山 マ ふ し マ うくの

#### Pseudo-particle self energy Feynman diagrams OCA (2nd order) diagrams:

$$=\sum_{\alpha_{1},\beta_{1}=1}^{n}\sum_{\alpha_{0},\beta_{0}=1}^{n}\int_{0}^{t}\mathrm{d}\tau_{2}\int_{0}^{\tau_{2}}\mathrm{d}\tau_{1}\,\Delta_{\alpha_{1}\beta_{1}}(t-\tau_{1})\,\Delta_{\alpha_{0}\beta_{0}}(\tau_{2})F_{\alpha_{1}}^{\dagger}G(t-\tau_{2})F_{\alpha_{0}}^{\dagger}G(\tau_{2}-\tau_{1})F_{\beta_{1}}G(\tau_{1})F_{\beta_{0}}$$

n: impurity size,  $\Delta : n \times n$  p.p. hybridization function,  $G : N \times N$  p.p. Green's function,  $F_{\alpha}, F_{\beta}^{\dagger} : N \times N$ : ED of impurty operators  $\hat{c}_{\alpha}, \hat{c}_{\beta}^{\dagger}$ .  $(\alpha, \beta = 1, \cdots, n.)$ 

#### TCA (third order) diagrams:

# Why is the calculation of these diagrams difficult: crossings of hybridization lines

- ▶ An *m*-th order diagram is a (2m 2)-dimensional integral.
- ▶ Direct calculation cost:  $O(n^{2m}\beta^{2m-2})$  for an *n*-th order diagram. (*n* is the impurity size.)
- ▶ If there are no crossing of hybridization lines:

$$= \int_{0}^{t} dt_{2} \int_{0}^{t_{2}} dt_{1} \Delta(t_{2}) F^{\dagger} G(t - t_{2}) F^{\dagger} G(t_{2} - t_{1}) F G(t_{1}) F$$
$$= \int_{0}^{t} dt_{2} F^{\dagger} G(t - t_{2}) F^{\dagger} \Delta(t_{2}) F \int_{0}^{t_{2}} dt_{1} G(t_{2} - t_{1}) F G(t_{1}) F.$$

▲□▶ ▲□▶ ▲目▶ ▲目▶ 目 のへで

▶ The 2D integral becomes two 1D integrals.

#### Cutting the hybridization

Decomposition of the hybridization function:

$$\Delta(t-t') = \sum_{l=1}^{r} c_l \mathrm{e}^{-\lambda_l t} \mathrm{e}^{\lambda_l t_1} =: \sum_{l=1}^{r} u_l(t) v_l(t_1).$$

$$\Delta(t-t') = \sum_{l=1}^{u_l} \mathbf{v}_l$$

$$\mathbf{t} = \sum_{l=1}^{u_l} \mathbf{v}_l$$

Take OCA diagrams as an example:

$$Consider \int_{0}^{t} dt_{2} \int_{0}^{t_{2}} dt_{1} \Delta(t-t_{1}) \Delta(t_{2}) G(t-t_{2}) G(t_{2}-t_{1}) G(t_{1}).$$

$$If \Delta(t-t_{1}) = \sum_{l=1}^{r} u_{l}(t) v_{l}(t_{1}), \text{ then the original integral becomes } u_{l}(t) \Delta(t_{2}) v_{l}(t_{1}),$$

$$\sum_{l=1}^{r} \int_{0}^{t} dt_{2} \int_{0}^{t_{2}} dt_{1} u_{l}(t) v_{l}(t_{1}) \Delta(t_{2}) G(t-t_{2}) G(t_{2}-t_{1}) G(t_{1}) = \sum_{l} \int_{0}^{t} u_{l}(t) \Delta(t_{2}) v_{l}(t_{1}),$$

$$= \sum_{l=1}^{r} u_{l}(t) \left( \int_{0}^{t} dt_{2} \Delta(t_{2}) G(t-t_{2}) \left( \int_{0}^{t_{2}} dt_{1} v_{l}(t_{1}) G(t_{2}-t_{1}) G(t_{1}) \right) \right) = \sum_{l} \int_{0}^{t} u_{l}(t) \Delta(t_{2}) v_{l}(t_{1}) \int_{0}^{t} dt_{2} \Delta(t_{2}) G(t-t_{2}) \left( \int_{0}^{t_{2}} dt_{1} v_{l}(t_{1}) G(t_{2}-t_{1}) G(t_{1}) \right) = \sum_{l} \int_{0}^{t} u_{l}(t) \Delta(t_{2}) v_{l}(t_{1}) \int_{0}^{t} dt_{2} \Delta(t_{2}) G(t-t_{2}) \left( \int_{0}^{t_{2}} dt_{1} v_{l}(t_{1}) G(t_{2}-t_{1}) G(t_{1}) \right) = \sum_{l} \int_{0}^{t} u_{l}(t) \Delta(t_{2}) v_{l}(t_{1}) \int_{0}^{t} dt_{2} \Delta(t_{2}) G(t-t_{2}) \left( \int_{0}^{t_{2}} dt_{1} v_{l}(t_{1}) G(t_{2}-t_{1}) G(t_{1}) \right) = \sum_{l} \int_{0}^{t} u_{l}(t) \Delta(t_{2}) v_{l}(t_{1}) \int_{0}^{t} dt_{2} \Delta(t_{2}) G(t-t_{2}) \left( \int_{0}^{t_{2}} dt_{1} v_{l}(t_{1}) G(t_{2}-t_{1}) G(t_{1}) \right) \int_{0}^{t} dt_{2} \Delta(t_{2}) G(t-t_{2}) \left( \int_{0}^{t} dt_{2} \Delta(t_{2}) G(t-t_{2})$$

#### Computational complexity

A pole fitting with r poles enables a hybridization of decomposition with nr terms:

$$\Delta(t - t_1) = \sum_{l=1}^{nr} u_l(t) v_l(t_1).$$

Computational cost for m-th order diagram:

$$O((nr)^{m-1}mr_0^2)$$
,  $r_0$  is the DLR rank.

Comparison:

$$n^{2m}\beta^{2m-2} \to (nr)^{m-1}mr_0^2.$$

$$r_0 = \log(\beta), \quad r < r_0,$$

#### Examples

Spinless dimer model: strongly correlated, exact solvable.

$$H = Uc_0^{\dagger}c_0c_1^{\dagger}c_1 - v\left(c_0^{\dagger}c_1 + c_1^{\dagger}c_0\right) - t\sum_{k=0}^{1}\sum_{i=0}^{1}\left(c_i^{\dagger}b_{ik} + \text{h.c.}\right) - t'\sum_{k=0}^{1}\left(b_{0k}^{\dagger}b_{1k} + \text{h.c.}\right),$$

Plot of  $G_{00}(\tau)^3$ . (For  $\beta = 16$ .)

# Runtime<sup>4 5</sup>

Spinless dimer (n = 2):

ppsc-soe (TCA)	ppsc-soe (4th order)	ppsc-soe (5th order)	Inchworm	CT-hyb
7.64 seconds	1 hour	90 hours	500 hours	12000 hours

And erson two-band model (n = 4):

ppsc-soe (TCA)	ppsc-soe (4th order)	Inchworm	CT-hyb
0.2 hours	22 hours	1000 hours	3000 hours

DMFT calculation for toy model of Ca<sub>2</sub>RuO<sub>4</sub> (n = 6): TCA: 59.7 core hours (for  $\beta = 10$ ). It takes 6 iterations to reach accuracy  $\varepsilon = 10^{-6}$ ). There are  $4 \times 2^3 \times 6^6 = 1492992$  5-dim integrals.

## Implementation

- ▶ Code is written in C++, based on cppdlr.
- ▶ Parallelizable: the evaluation of  $(np)^{m-1}$  terms could be done simultaneously.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

- ▶ Easy to use: python interface.
- ▶ TRIQS compatible.

# Conclusion and outlook

Fast impurity solver:

- Robust, high-order accurate diagram evaluation possible beyond typical lowest-order approximations. Free of sign problem.
- Access to low temperature.
- Code ready to be tested on applications.

#### Bath fitting scheme:

- ▶ Python package (Adapol) available.
- ▶ TRIQS interface.

Ongoing work:

- Real-time bath fitting, real-time Feynman diagrams, real-time impurity solvers.
- ► Analytic continuation of continuous spectrum.
- ▶ Connections to Tensor Cross Interpolation (TCI).

▶ More software development ...

Thank you for your attention!
