University of California, Berkeley

January 9, 2014

Project Overview

We examine optimal portfolio allocation with transaction constraints via duality methods

- Various models of asset returns and transaction costs
- Correlations and uncertainty in estimated parameters
- General algorithm to solve dual portfolio allocation problem.

Project Overview

We examine optimal portfolio allocation with transaction constraints via duality methods

- Various models of asset returns and transaction costs
- Correlations and uncertainty in estimated parameters
- General algorithm to solve dual portfolio allocation problem.

Rapidly approximate optimal allocations with a large number of assets and uncertain parameters.

Problem Description

Single-period investment model with n assets:

- Risk-return preference: $f = f_1 + \cdots + f_n$,
- Transaction costs: $g = g_1 + \cdots + g_n$,
- Investment constraint: $w_i \in [\underline{w}_i, \overline{w}_i] = \mathcal{W}_i$.

Problem Description

Single-period investment model with n assets:

- Risk-return preference: $f = f_1 + \cdots + f_n$,
- Transaction costs: $g = g_1 + \cdots + g_n$,
- Investment constraint: $w_i \in [\underline{w}_i, \overline{w}_i] = \mathcal{W}_i$.

Assume that we can rapidly optimize:

$$\min_{w_i \in \mathcal{W}_i} f_i(w_i) + \lambda g_i(w_i).$$

Lagrangian Relaxation

In general, we consider an investment problem of the form:

$$p^* = \min_{w \in \mathcal{W}} \{f(w) : g(w) \leq \tau\}.$$

Lagrangian Relaxation

In general, we consider an investment problem of the form:

$$p^* = \min_{w \in \mathcal{W}} \{f(w) : g(w) \leq \tau\}.$$

In this project, we consider the related problem:

$$d^* = \max_{\lambda \geq 0} \min_{w \in \mathcal{W}} \mathcal{L}(w, \lambda)$$

where $\mathcal{L}(w, \lambda) = f(w) + \lambda(g(w) - \tau)$.

Lagrangian Relaxation

Proposition

With the dual problem defined as above, $p^ \geq d^*$.*

Lagrangian Relaxation

Proposition

With the dual problem defined as above, $p^ \geq d^*$.*

Proof.

Let $w^* \in \mathcal{W}$ such that $g(w^*) \leq \tau$ and $f(w^*) = p^*$.

Lagrangian Relaxation

Proposition

With the dual problem defined as above, $p^ \geq d^*$.*

Proof.

Let $w^* \in \mathcal{W}$ such that $g(w^*) \leq \tau$ and $f(w^*) = p^*$. For all $\lambda \geq 0$,

$$\begin{aligned} p^* &\geq f(w^*) + \lambda(g(w^*) - \tau) \\ &\geq \min_{w \in \mathcal{W}} \{f(w) + \lambda(g(w) - \tau)\}. \end{aligned}$$

Lagrangian Relaxation

Proposition

With the dual problem defined as above, $p^ \geq d^*$.*

Proof.

Let $w^* \in \mathcal{W}$ such that $g(w^*) \leq \tau$ and $f(w^*) = p^*$. For all $\lambda \geq 0$,

$$\begin{aligned} p^* &\geq f(w^*) + \lambda(g(w^*) - \tau) \\ &\geq \min_{w \in \mathcal{W}} \{f(w) + \lambda(g(w) - \tau)\}. \end{aligned}$$

Then

$$p^* \geq \max_{\lambda \geq 0} \min_{w \in \mathcal{W}} \mathcal{L}(w, \lambda) = d^*.$$

Binary Model

In the binary model, we have fixed transaction costs for purchases and disallow short-sales:

$$g_i(\xi) = \begin{cases} +\infty & \text{if } \xi < 0 \\ 0 & \text{if } \xi = 0 \\ b_i & \text{if } \xi > 0. \end{cases}$$

Binary Model

In the binary model, we have fixed transaction costs for purchases and disallow short-sales:

$$g_i(\xi) = \begin{cases} +\infty & \text{if } \xi < 0 \\ 0 & \text{if } \xi = 0 \\ b_i & \text{if } \xi > 0. \end{cases}$$

Theorem

We can construct an optimal solution (λ^, w^*) to the dual problem in the binary model in time $O(n)$.*

Binary Model

In the binary model, we have fixed transaction costs for purchases and disallow short-sales:

$$g_i(\xi) = \begin{cases} +\infty & \text{if } \xi < 0 \\ 0 & \text{if } \xi = 0 \\ b_i & \text{if } \xi > 0. \end{cases}$$

Theorem

We can construct an optimal solution (λ^, w^*) to the dual problem in the binary model in time $O(n)$.*

Corollary

There is no duality gap in the binary model with unit transaction costs and integer-valued τ .

Binary Model

Theorem

We can construct an optimal solution (λ^, w^*) to the dual problem in the binary model in time $O(n)$.*

Binary Model

Theorem

We can construct an optimal solution (λ^, w^*) to the dual problem in the binary model in time $O(n)$.*

Proof

$$d^* = \max_{\lambda \geq 0} \min_{w \in \mathcal{W}} \{f(w) + \lambda(g(w) - \tau)\}$$

Binary Model

Theorem

We can construct an optimal solution (λ^, w^*) to the dual problem in the binary model in time $O(n)$.*

Proof

$$\begin{aligned} d^* &= \max_{\lambda \geq 0} \min_{w \in \mathcal{W}} \{f(w) + \lambda(g(w) - \tau)\} \\ &= \max_{\lambda \geq 0} \left\{ -\lambda\tau + \sum_{i=1}^n \min_{w_i \in \mathcal{W}_i} f_i(w_i) + \lambda g_i(w_i) \right\} \end{aligned}$$

Binary Model

Theorem

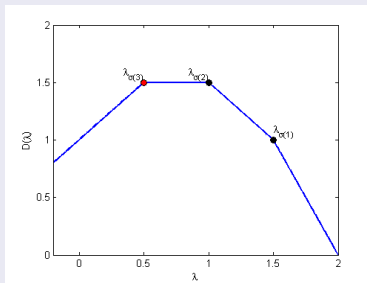

We can construct an optimal solution (λ^, w^*) to the dual problem in the binary model in time $O(n)$.*

Proof

$$\begin{aligned} d^* &= \max_{\lambda \geq 0} \min_{w \in \mathcal{W}} \{f(w) + \lambda(g(w) - \tau)\} \\ &= \max_{\lambda \geq 0} \left\{ -\lambda\tau + \sum_{i=1}^n \min_{w_i \in \mathcal{W}_i} f_i(w_i) + \lambda g_i(w_i) \right\} \\ &= \max_{\lambda \geq 0} \left\{ -\lambda\tau + \sum_{i=1}^n \min \left\{ f_i(0), \lambda b_i + \min_{0 < w_i \leq \bar{w}_i} f_i(w_i) \right\} \right\}. \end{aligned}$$

Binary Model

$$d^* = \max_{\lambda \geq 0} \left\{ -\lambda\tau + \sum_{i=1}^n \min \{ f_i^0, \lambda b_i + f_i^+ \} \right\}.$$

Maximization in $O(n)$ via Quickselect algorithm.

Ternary Model

In the ternary model, we have fixed transaction costs for both purchases and sales:

$$g_i(\xi) = \begin{cases} s_i & \text{if } \xi < 0 \\ 0 & \text{if } \xi = 0 \\ b_i & \text{if } \xi > 0. \end{cases}$$

Furthermore, let us assume that we have the restriction on τ that

$$0 \leq \tau \leq \sum_{i=1}^n \max(s_i, b_i).$$

Ternary Model

Proposition

The solution of the dual problem under the ternary model may be written

$$d^* = 1^\top f^0 + \min_{u^\pm} \left\{ (h^+)^\top u^+ + (h^-)^\top u^- : u^\pm \geq 0, \right. \\ \left. u^+ + u^- \leq 1, \right. \\ \left. b^\top u^+ + s^\top u^- \leq \tau \right\}$$

for appropriate vectors f^0 , h^+ , and h^- .

Ternary Model

Proposition

The solution of the dual problem under the ternary model may be written

$$d^* = 1^\top f^0 + \min_{u^\pm} \left\{ (h^+)^\top u^+ + (h^-)^\top u^- : u^\pm \geq 0, \right. \\ \left. u^+ + u^- \leq 1, \right. \\ \left. b^\top u^+ + s^\top u^- \leq \tau \right\}$$

for appropriate vectors f^0 , h^+ , and h^- .

Theorem

We can construct an optimal solution (λ^, w^*) to the dual problem in the ternary model in polynomial time.*

Ternary Model

Proposition

In the ternary model, it is not true that $p^ = d^*$ in general.*

Ternary Model

Proposition

In the ternary model, it is not true that $p^ = d^*$ in general.*

Proposition

Let (λ^, w^*) be an optimal solution to the dual problem obtained from the algorithm above. Then the duality gap is bounded by*

$$0 \leq p^* - d^* \leq \lambda^* (\tau - g(w^*)).$$

Correlation Model

In the correlation model, we consider an objective function:

$$f(w, \hat{r}) = \frac{1}{2} w^\top \Sigma w - \hat{r}^\top w,$$

where $\hat{r} \in \mathcal{R} \subset \mathbb{R}^n$ contains predicted returns and Σ is an estimate of the covariance matrix.

Correlation Model

In the correlation model, we consider an objective function:

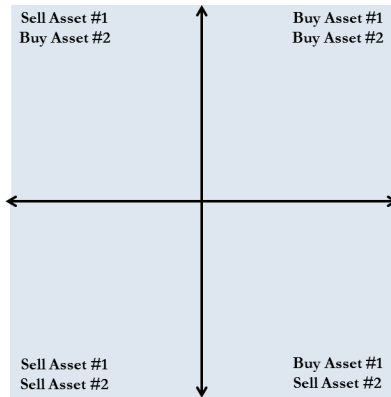

$$f(w, \hat{r}) = \frac{1}{2} w^\top \Sigma w - \hat{r}^\top w,$$

where $\hat{r} \in \mathcal{R} \subset \mathbb{R}^n$ contains predicted returns and Σ is an estimate of the covariance matrix.

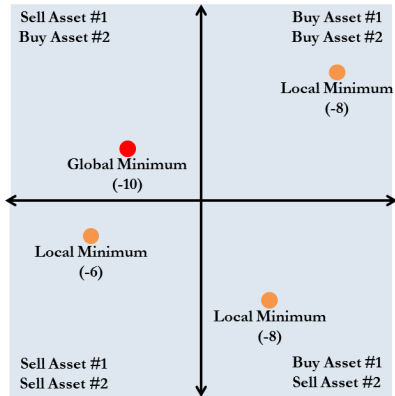

The corresponding dual problem is:

$$d^* = \max_{\lambda \geq 0} \min_{w \in \mathcal{W}} \max_{\hat{r} \in \mathcal{R}} \{f(w, \hat{r}) + \lambda(g(w) - \tau)\}$$

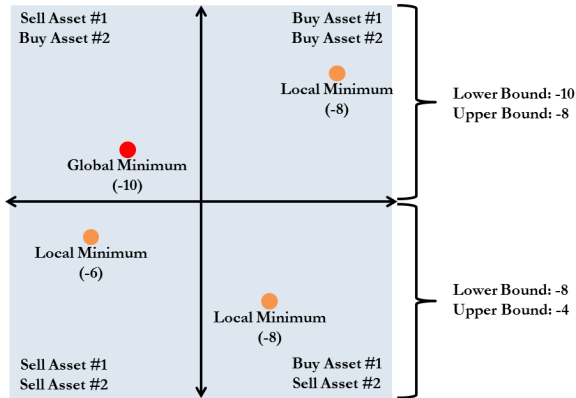

Branch-and-Bound Method

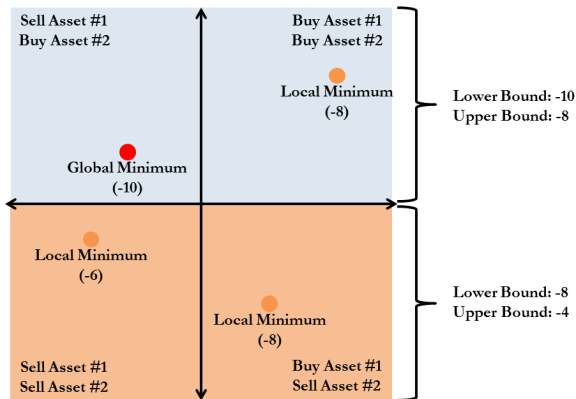

Branch-and-Bound Method

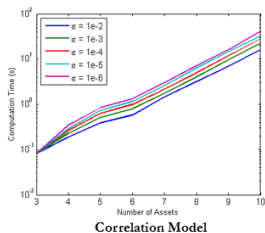

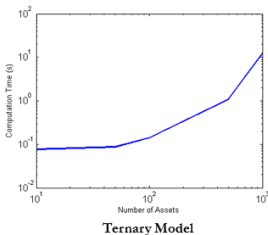

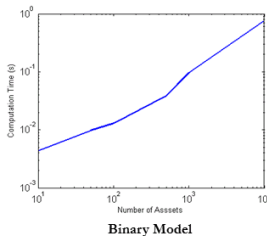

Branch-and-Bound Method

Branch-and-Bound Method

Numerical Tests

Tested under extra condition that $\sum_{i=1}^n w_i \leq 1$.

Conclusions

Duality methods provide approximate allocations in difficult portfolio optimization problems:

- Usefulness of decomposability
- Opportunities for parallelization in branch-and-bound methods
- Approximate solution as input to solver for the primal problem.
